Flask-Admin documentation

Release 1.3.0

Serge S. Koval

August 30, 2015

Contents

Why Flask? As a micro-framework, Flask lets you build web services with very little overhead. It offers freedom for you, the designer, to implement your project in a way that suits your particular application.

Why Flask-Admin? In a world of micro-services and APIs, Flask-Admin solves the boring problem of building an admin interface on top of an existing data model. With little effort, it lets you manage your web service's data through a user-friendly interface.

How does it work? The basic concept behind Flask-Admin, is that it lets you build complicated interfaces by grouping individual views together in classes: Each web page you see on the frontend, represents a method on a class that has explicitly been added to the interface.

These view classes are especially helpful when they are tied to particular database models, because they let you group together all of the usual *Create, Read, Update, Delete* (CRUD) view logic into a single, self-contained class for each of your models.

What does it look like? At http://examples.flask-admin.org/ you can see some examples of Flask-Admin in action, or browse through the *examples/* directory in the GitHub repository.

Introduction To Flask-Admin

1.1 Getting Started

1.1.1 Initialization

The first step, is to initialise an empty admin interface on your Flask app:

```python
from flask import Flask
from flask_admin import Admin

app = Flask(__name__)

admin = Admin(app, name='microblog', template_mode='bootstrap3')
# Add administrative views here

app.run()
```

Here, both the *name* and *template_mode* parameters are optional. Alternatively, you could use the *init_app()* method.

If you start this application and navigate to http://localhost:5000/admin/, you should see an empty page with a navigation bar on top.

1.1.2 Adding Model Views

Model views allow you to add a dedicated set of admin pages for managing any model in your database. Do this by creating instances of the *ModelView* class, which you can import from one of Flask-Admin's built-in ORM backends. An example is the SQLAlchemy backend, which you can use as follows:

```python
from flask_admin.contrib.sqla import ModelView

# Flask and Flask-SQLAlchemy initialization here

admin = Admin(app, name='microblog', template_mode='bootstrap3')
admin.add_view(ModelView(User, db.session))
admin.add_view(ModelView(Post, db.session))
```

Straight out of the box, this gives you a set of fully featured *CRUD* views for your model:

- A *list* view, with support for searching, sorting and filtering and deleting records.

- A *create* view for adding new records.
- An *edit* view for updating existing records.
- An optional, read-only *detail* view.

There are many options available for customizing the display and functionality of these builtin views. For more details on that, see *Customising Builtin Views*. For more details on the other ORM backends that are available, see *Using Different Database Backends*.

1.1.3 Enabling CSRF Validation

To add CSRF protection to the forms that are generated by *ModelView* instances, use the FlaskWTF form class in your *ModelView* subclass by specifying the *form_base_class* parameter:

```python
from flask_admin.contrib.sqla import ModelView
import flask_wtf

# Flask and Flask-SQLAlchemy initialization here

app.config['CSRF_ENABLED'] = True
flask_wtf.CsrfProtect(app)

class MicroBlogModelView(ModelView):
    form_base_class = flask_wtf.Form
```

The FlaskWTF form class comes with CSRF protection builtin, so it will generate the tokens for you, and validate them when the forms are submitted.

1.1.4 Adding Content to the Index Page

The first thing you'll notice when you visit http://localhost:5000/admin/ is that it's just an empty page with a navigation menu. To add some content to this page, save the following text as *admin/index.html* in your project's *templates* directory:

```
{% extends 'admin/master.html' %}

{% block body %}
  <p>Hello world</p>
{% endblock %}
```

This will override the default index template, but still give you the builtin navigation menu. So, now you can add any content to the index page, while maintaining a consistent user experience.

1.2 Authorisation & Permissions

When setting up an admin interface for your application, one of the first problems you'll want to solve is how to keep unwanted users out. With Flask-Admin there are a few different ways of approaching this.

1.2.1 HTTP Basic Auth

The simplest form of authentication is HTTP Basic Auth. It doesn't interfere with your database models, and it doesn't require you to write any new view logic or template code. So it's great for when you're deploying something that's still under development, before you want the whole world to see it.

Have a look at Flask-BasicAuth to see just how easy it is to put your whole application behind HTTP Basic Auth.

Unfortunately, there is no easy way of applying HTTP Basic Auth just to your admin interface.

1.2.2 Rolling Your Own

For a more flexible solution, Flask-Admin lets you define access control rules on each of your admin view classes by simply overriding the *is_accessible* method. How you implement the logic is up to you, but if you were to use a low-level library like Flask-Login, then restricting access could be as simple as:

```
class MicroBlogModelView(sqla.ModelView):

    def is_accessible(self):
        return login.current_user.is_authenticated()

    def inaccessible_callback(self, name, **kwargs):
        # redirect to login page if user doesn't have access
        return redirect(url_for('login', next=request.url))
```

In the navigation menu, components that are not accessible to a particular user will not be displayed for that user. For an example of using Flask-Login with Flask-Admin, have a look at https://github.com/flask-admin/Flask-Admin/tree/master/examples/auth-flask-login.

The main drawback is that you still need to implement all of the relevant login, registration and account management views yourself.

1.2.3 Using Flask-Security

If you want a more polished solution, you could use Flask-Security, which is a higher-level library. It comes with lots of builtin views for doing common things like user registration, login, email address confirmation, password resets, etc.

The only complicated bit, is making the builtin Flask-Security views integrate smoothly with the Flask-Admin templates to create a consistent user experience. To do this, you will need to override the builtin Flask-Security templates and have them extend the Flask-Admin base template by adding the following to the top of each file:

```
{% extends 'admin/master.html' %}
```

Now, you'll need to manually pass in some context variables for the Flask Admin templates to render correctly when they're being called from the Flask-Security views. Defining a *security_context_processor* function will take care of this for you:

```
def security_context_processor():
    return dict(
        admin_base_template=admin.base_template,
        admin_view=admin.index_view,
        h=admin_helpers,
    )
```

For a working example of using Flask-Security with Flask-Admin, have a look at https://github.com/flask-admin/Flask-Admin/tree/master/examples/auth.

The example only uses the builtin *register* and *login* views, but you could follow the same approach for including the other views, like *forgot_password*, *send_confirmation*, etc.

1.3 Customising Builtin Views

The builtin *ModelView* class is great for getting started quickly. But you'll want to configure its functionality to suit your particular models. This is done by setting values for the configuration attributes that are made available on the *ModelView* class.

To specify some global configuration parameters, you can subclass *ModelView*, and then use that subclass when adding your models to the interface:

```python
from flask_admin.contrib.sqla import ModelView

# Flask and Flask-SQLAlchemy initialization here

class MicroBlogModelView(ModelView):
    can_delete = False  # disable model deletion
    page_size = 50  # the number of entries to display on the list view

admin.add_view(MicroBlogModelView(User, db.session))
admin.add_view(MicroBlogModelView(Post, db.session))
```

Or, in much the same way, you can specify options for a single model at a time:

```python
class UserView(ModelView):
        can_delete = False  # disable model deletion

class PostView(ModelView):
        page_size = 50  # the number of entries to display on the list view

admin.add_view(UserView(User, db.session))
admin.add_view(PostView(Post, db.session))
```

1.3.1 *ModelView* Configuration Attributes

For a complete list of the attributes that are defined, have a look at the API documentation for *BaseModelView()*. Here follows some of the most commonly used ones:

To **disable some of the CRUD operations**, set any of these boolean parameters:

```python
can_create = False
can_edit = False
can_delete = False
```

If your model has too much data to display in the list view, you can **add a read-only detail view** by setting:

```python
can_view_details = True
```

Removing columns from the list view is easy, just pass a list of column names for the *column_excludes_list* parameter:

```python
column_exclude_list = ['password', ]
```

To **make columns searchable**, or to use them for filtering, specify a list of column names:

```
column_searchable_list = ['name', 'email']
column_filters = ['country', ]
```

For a faster editing experience, enable **inline editing** in the list view:

```
column_editable_list = ['name', 'last_name']
```

Or, have the add & edit forms display inside a **modal window** on the list page, in stead of on the dedicated *create & edit* pages:

```
create_modal = True
edit_modal = True
```

You can restrict the possible values for a text-field by specifying a list of **select choices**:

```
form_choices = {
    'title': [
        ('MR', 'Mr'),
        ('MRS', 'Mrs'),
        ('MS', 'Ms'),
        ('DR', 'Dr'),
        ('PROF', 'Prof.')
    ]
}
```

To **remove fields** from the create and edit forms:

```
form_excluded_columns = ['last_name', 'email']
```

To specify **WTForms field arguments**:

```
form_args = {
    'name': {
        'label': 'First Name',
        'validators': [required()]
    }
}
```

Or, to specify arguments to the **WTForms widgets** used to render those fields:

```
form_widget_args = {
    'description': {
        'rows': 10,
        'style': 'color: black'
    }
}
```

When your forms contain foreign keys, have those **related models loaded via ajax**, using:

```
form_ajax_refs = {
    'user': {
        'fields': ['first_name', 'last_name', 'email'],
        'page_size': 10
    }
}
```

To **manage related models inline**:

```
inline_models = ['post', ]
```

These inline forms can be customised. Have a look at the API documentation for *inline_models()*.

1.4 Adding Your Own Views

For situations where your requirements are really specific and you struggle to meet them with the builtin `ModelView` class, Flask-Admin makes it easy for you to take full control and add your own views to the interface.

1.4.1 Standalone Views

A set of standalone views, that are not tied to any particular model, can be added by extending the *BaseView* class, and defining your own view methods on it. For example, to add a page that displays some analytics data from a 3rd-party API:

```python
from flask_admin import BaseView, expose

class AnalyticsView(BaseView):
    @expose('/')
    def index(self):
        return self.render('analytics_index.html')

admin.add_view(CustomView(name='Analytics', endpoint='analytics'))
```

This will add a link to the navbar, from where your view can be accessed. Notice that it is served at '/', the root URL. This is a restriction on standalone views: at the very minimum, each view class needs at least one method to serve a view at its root.

The *analytics_index.html* template for the example above, could look something like:

```
{% extends 'admin/master.html' %}
{% block body %}
  <p>Here I'm going to display some data.</p>
{% endblock %}
```

By extending the *admin/master.html* template, you can maintain a consistent user experience, even while having tight control over your page's content.

1.4.2 Overriding The Builtin Views

There may be some scenarios where you want most of the builtin ModelView functionality, but you want to replace one of the default *create*, *edit*, or *list* views. For this you could override only the view in question, and all the links to it will still function as you would expect:

```python
from flask_admin.contrib.sqla import ModelView

# Flask and Flask-SQLAlchemy initialization here

class UserView(ModelView):
    @expose('/new/', methods=('GET', 'POST'))
    def create_view(self):
        """
        Custom create view.
        """

        return self.render('create_user.html')
```

1.5 Working With The Builtin Templates

Flask-Admin uses the Jinja2 templating engine.

1.5.1 Overriding The Builtin Templates

To take full control over the style and layout of the admin interface, you can override all of the builtin templates. Just keep in mind that the templates will change slightly from one version of Flask-Admin to the next, so once you start overriding them, you need to take care when upgrading your package version.

To override any of the builtin templates, simply copy them from the Flask-Admin source into your project's *templates/admin/* directory. As long as the filenames stay the same, the templates in your project directory should automatically take precedence over the builtin ones.

1.5.2 Extending The Builtin Templates

Rather than overriding the builtin templates completely, you could extend them. This could make it simpler for you to upgrade to new Flask Admin versions in future.

Internally, the Flask-Admin templates are derived from the *admin/master.html* template. The three most interesting templates for you to extend are probably:

- *admin/model/list.html*
- *admin/model/create.html*
- *admin/model/edit.html*

To extend the default *edit* template with your own functionality, create a template in *templates/microblog_edit.html* to look something like:

```
{% extends 'admin/model/edit.html' %}

{% block body %}
    <h1>MicroBlog Edit View</h1>
    {{ super() }}
{% endblock %}
```

Now, to make your view classes use this template, set the appropriate class property:

```
class MicroBlogModelView(ModelView):
    edit_template = 'microblog_edit.html'
    # create_template = 'microblog_create.html'
    # list_template = 'microblog_list.html'
```

If you want to use your own base template, then pass the name of the template to the admin constructor during initialization:

```
admin = Admin(app, base_template='microblog_master.html')
```

Available Template Blocks

Flask-Admin defines one *base* template at *admin/master.html* that all the other admin templates are derived from. This template is a proxy which points to *admin/base.html*, which defines the following blocks:

Block Name	Description
head_meta	Page metadata in the header
title	Page title
head_css	Various CSS includes in the header
head	Empty block in HTML head, in case you want to put something there
page_body	Page layout
brand	Logo in the menu bar
main_menu	Main menu
menu_links	Links menu
access_control	Section to the right of the menu (can be used to add login/logout buttons)
messages	Alerts and various messages
body	Content (that's where your view will be displayed)
tail	Empty area below content

In addition to all of the blocks that are inherited from *admin/master.html*, the *admin/model/list.html* template also contains the following blocks:

Block Name	Description
model_menu_bar	Menu bar
model_list_table	Table container
list_header	Table header row
list_row_actions_header	Actions header
list_row	Single row
list_row_actions	Row action cell with edit/remove/etc buttons
empty_list_message	Message that will be displayed if there are no models found

Have a look at the *layout* example at https://github.com/flask-admin/flask-admin/tree/master/examples/layout to see how you can take full stylistic control over the admin interface.

1.5.3 Environment Variables

While working in any of the templates that extend *admin/master.html*, you have access to a small number of environment variables:

Variable Name	Description
admin_view	Current administrative view
admin_base_template	Base template name
_gettext	Babel gettext
_ngettext	Babel ngettext
h	Helpers from *helpers* module

1.5.4 Generating URLs

To generate the URL for a specific view, use *url_for* with a dot prefix:

```python
from flask import url_for

class MyView(BaseView):
    @expose('/')
    def index(self):
        # Get URL for the test view method
        user_list_url = url_for('user.index_view')
        return self.render('index.html', user_list_url=user_list_url)
```

A specific record can also be referenced with:

```
# Edit View for record #1 (redirect back to index_view)
url_for('user.edit_view', id=1, url=url_for('user.index_view'))
```

When referencing ModelView instances, use the lowercase name of the model as the prefix when calling *url_for*. Other views can be referenced by specifying a unique endpoint for each, and using that as the prefix. So, you could use:

```
url_for('analytics.index')
```

If your view endpoint was defined like:

```
admin.add_view(CustomView(name='Analytics', endpoint='analytics'))
```

Advanced Functionality

2.1 Localization With Flask-Babelex

Flask-Admin comes with translations built-in for several languages. Enabling localization is simple:

1. Install Flask-BabelEx to do the heavy lifting. It's a fork of the Flask-Babel package:

   ```
   pip install flask-babelex
   ```

2. Initialize Flask-BabelEx by creating instance of *Babel* class:

   ```python
   from flask import app
   from flask_babelex import Babel

   app = Flask(__name__)
   babel = Babel(app)
   ```

3. Create a locale selector function:

   ```python
   @babel.localeselector
   def get_locale():
       if request.args.get('lang'):
           session['lang'] = request.args.get('lang')
       return session.get('lang', 'en')
   ```

   Now, you could try out a French version of the application at: http://localhost:5000/admin/?lang=fr.

Go ahead and add your own logic to the locale selector function. The application could store locale in a user profile, cookie, session, etc. And it could interrogate the *Accept-Language* header for making the selection automatically.

If the builtin translations are not enough, look at the Flask-BabelEx documentation to see how you can add your own.

2.2 Managing Files & Folders

To manage static files, that are not tied to your db model, Flask-Admin comes with the FileAdmin plugin. It gives you the ability to upload, delete, rename, etc. You can use it by adding a FileAdmin view to your app:

```
from flask_admin.contrib.fileadmin import FileAdmin

import os.path as op

# Flask setup here

admin = Admin(app, name='microblog', template_mode='bootstrap3')

path = op.join(op.dirname(__file__), 'static')
admin.add_view(FileAdmin(path, '/static/', name='Static Files'))
```

You can disable uploads, disable file deletion, restrict file uploads to certain types, etc. Check *flask_admin.contrib.fileadmin* in the API documentation for more details.

2.3 Adding A Redis Console

Another plugin that's available, is the Redis Console. If you have a Redis instance running on the same machine as your app, you can:

```
from redis import Redis
from flask_admin.contrib import rediscli

# Flask setup here

admin = Admin(app, name='microblog', template_mode='bootstrap3')

path = op.join(op.dirname(__file__), 'static')
admin.add_view(rediscli.RedisCli(Redis()))
```

2.4 Replacing Individual Form Fields

The *form_overrides* attribute allows you to replace individual fields within a form. A common use-case for this would be to add a *What-You-See-Is-What-You-Get* (WYSIWIG) editor, or to handle file / image uploads that need to be tied to a field in your model.

2.4.1 WYSIWIG Text Fields

To handle complicated text content, you can use CKEditor by subclassing some of the builtin WTForms classes as follows:

```
from wtforms import TextAreaField
from wtforms.widgets import TextArea

class CKTextAreaWidget(TextArea):
    def __call__(self, field, **kwargs):
        if kwargs.get('class'):
            kwargs['class'] += ' ckeditor'
        else:
```

```
            kwargs.setdefault('class', 'ckeditor')
        return super(CKTextAreaWidget, self).__call__(field, **kwargs)

class CKTextAreaField(TextAreaField):
    widget = CKTextAreaWidget()

class MessageAdmin(ModelView):
    form_overrides = {
        'body': CKTextAreaField
    }
    create_template = 'ckeditor.html'
    edit_template = 'ckeditor.html'
```

For this to work, you would also need to create a template that extends the default functionality by including the necessary CKEditor javascript on the *create* and *edit* pages. Save this in *templates/ckeditor.html*:

```
{% extends 'admin/model/edit.html' %}

{% block tail %}
  {{ super() }}
  <script src="//cdn.ckeditor.com/4.5.1/standard/ckeditor.js"></script>
{% endblock %}
```

2.4.2 File & Image Fields

Flask-Admin comes with a builtin *FileUploadField()* and *ImageUploadField()*. To make use of them, you'll need to specify an upload directory, and add them to the forms in question. Image handling also requires you to have Pillow installed if you need to do any processing on the image files.

Have a look at the example at https://github.com/flask-admin/Flask-Admin/tree/master/examples/forms.

If you are using the MongoEngine backend, Flask-Admin supports GridFS-backed image- and file uploads, done through WTForms fields. Documentation can be found at *flask_admin.contrib.mongoengine.fields*.

If you just want to manage static files in a directory, without tying them to a database model, then rather use the handy *File-Admin* plugin.

2.5 Managing Geographical Models

If you want to store spatial information in a GIS database, Flask-Admin has you covered. The GeoAlchemy backend extends the SQLAlchemy backend (just as GeoAlchemy extends SQLAlchemy) to give you a pretty and functional map-based editor for your admin pages.

Some notable features include:

- Maps are displayed using the amazing Leaflet Javascript library, with map data from Mapbox.

- Geographic information, including points, lines and polygons, can be edited interactively using Leaflet.Draw.

- Graceful fallback: GeoJSON data can be edited in a `<textarea>`, if the user has turned off Javascript.

- Works with a Geometry SQL field that is integrated with Shapely objects.

To get started, define some fields on your model using GeoAlchemy's *Geometry* field. An then, add model views to your interface using the ModelView class from the GeoAlchemy backend, rather than the usual SQLAlchemy backend:

```python
from geoalchemy2 import Geometry
from flask_admin.contrib.geoa import ModelView

# .. flask initialization
db = SQLAlchemy(app)

class Location(db.Model):
    id = db.Column(db.Integer, primary_key=True)
    name = db.Column(db.String(64), unique=True)
    point = db.Column(Geometry("POINT"))
```

Some of the Geometry field types that are available include: "POINT", "MULTIPOINT", "POLYGON", "MULTI-POLYGON", "LINESTRING" and "MULTILINESTRING".

Have a look at https://github.com/flask-admin/flask-admin/tree/master/examples/geo_alchemy to get started.

2.5.1 Loading Tiles From Mapbox

To have map data display correctly, you'll have to sign up for an account at https://www.mapbox.com/ and include some credentials in your application's config:

```python
app = Flask(__name__)
app.config['MAPBOX_MAP_ID'] = "example.abc123"
app.config['MAPBOX_ACCESS_TOKEN'] = "pk.def456"
```

Leaflet supports loading map tiles from any arbitrary map tile provider, but at the moment, Flask-Admin only supports Mapbox. If you want to use other providers, make a pull request!

2.5.2 Limitations

There's currently no way to sort, filter, or search on geometric fields in the admin. It's not clear that there's a good way to do so. If you have any ideas or suggestions, make a pull request!

2.6 Customising Builtin Forms Via Rendering Rules

Before version 1.0.7, all model backends were rendering the *create* and *edit* forms using a special Jinja2 macro, which was looping over the fields of a WTForms form object and displaying them one by one. This works well, but it is difficult to customize.

Starting from version 1.0.7, Flask-Admin supports form rendering rules, to give you fine grained control of how the forms for your modules should be displayed.

The basic idea is pretty simple: the customizable rendering rules replace a static macro, so that you can tell Flask-Admin how each form should be rendered. As an extension, however, the rendering rules also let you do a bit more: You can use them to output HTML, call Jinja2 macros, render fields and so on.

Essentially, form rendering rules abstract the rendering, so that it becomes separate from the form definition. So, for example, it no longer matters in which sequence your form fields are defined.

To start using the form rendering rules, put a list of form field names into the *form_create_rules* property one of your admin views:

```python
class RuleView(sqla.ModelView):
    form_create_rules = ('email', 'first_name', 'last_name')
```

In this example, only three fields will be rendered and *email* field will be above other two fields.

Whenever Flask-Admin sees a string value in *form_create_rules*, it automatically assumes that it is a form field reference and creates a `flask_admin.form.rules.Field` class instance for that field.

Lets say we want to display some text between the *email* and *first_name* fields. This can be accomplished by using the `flask_admin.form.rules.Text` class:

```python
from flask_admin.form import rules

class RuleView(sqla.ModelView):
    form_create_rules = ('email', rules.Text('Foobar'), 'first_name', 'last_name')
```

2.6.1 Built-in Rules

Flask-Admin comes with few built-in rules that can be found in the `flask_admin.form.rules` module:

Form Rendering Rule	Description
flask_admin.form.rules.BaseRule	All rules derive from this class
flask_admin.form.rules.NestedRule	Allows rule nesting, useful for HTML containers
flask_admin.form.rules.Text	Simple text rendering rule
flask_admin.form.rules.HTML	Same as *Text* rule, but does not escape the text
flask_admin.form.rules.Macro	Calls macro from current Jinja2 context
flask_admin.form.rules.Container	Wraps child rules into container rendered by macro
flask_admin.form.rules.Field	Renders single form field
flask_admin.form.rules.Header	Renders form header
flask_admin.form.rules.FieldSet	Renders form header and child rules

2.7 Using Different Database Backends

Other than SQLAlchemy... There are five different backends for you to choose from, depending on which database you would like to use for your application. If, however, you need to implement your own database backend, have a look at *Adding A Model Backend*.

If you don't know where to start, but you're familiar with relational databases, then you should probably look at using *SQLAlchemy*. It is a full-featured toolkit, with support for SQLite, PostgreSQL, MySQL, Oracle and MS-SQL amongst others. It really comes into its own once you have lots of data, and a fair amount of relations between your data models. If you want to track spatial data like latitude/longitude points, you should look into GeoAlchemy, as well.

2.7.1 SQLAlchemy

Notable features:

- SQLAlchemy 0.6+ support
- Paging, sorting, filters
- Proper model relationship handling

- Inline editing of related models

Multiple Primary Keys

Flask-Admin has limited support for models with multiple primary keys. It only covers specific case when all but one primary keys are foreign keys to another model. For example, model inheritance following this convention.

Lets Model a car with its tyres:

```python
class Car(db.Model):
    __tablename__ = 'cars'
    id = db.Column(db.Integer, primary_key=True, autoincrement=True)
    desc = db.Column(db.String(50))

    def __unicode__(self):
        return self.desc

class Tyre(db.Model):
    __tablename__ = 'tyres'
    car_id = db.Column(db.Integer, db.ForeignKey('cars.id'), primary_key=True)
    tyre_id = db.Column(db.Integer, primary_key=True)
    car = db.relationship('Car', backref='tyres')
    desc = db.Column(db.String(50))
```

A specific tyre is identified by using the two primary key columns of the `Tyre` class, of which the `car_id` key is itself a foreign key to the class `Car`.

To be able to CRUD the `Tyre` class, you need to enumerate columns when defining the AdminView:

```python
class TyreAdmin(sqla.ModelView):
    form_columns = ['car', 'tyre_id', 'desc']
```

The `form_columns` needs to be explicit, as per default only one primary key is displayed.

When having multiple primary keys, **no** validation for uniqueness *prior* to saving of the object will be done. Saving a model that violates a unique-constraint leads to an Sqlalchemy-Integrity-Error. In this case, `Flask-Admin` displays a proper error message and you can change the data in the form. When the application has been started with `debug=True` the `werkzeug` debugger will catch the exception and will display the stacktrace.

2.7.2 MongoEngine

If you're looking for something simpler than SQLAlchemy, and your data models are reasonably self-contained, then MongoDB, a popular *NoSQL* database, could be a better option.

MongoEngine is a python wrapper for MongoDB. For an example of using MongoEngine with Flask-Admin, see https://github.com/flask-admin/flask-admin/tree/master/examples/mongoengine.

Features:

- MongoEngine 0.7+ support

- Paging, sorting, filters, etc

- Supports complex document structure (lists, subdocuments and so on)

- GridFS support for file and image uploads

In order to use MongoEngine integration, install the Flask-MongoEngine package. Flask-Admin uses form scaffolding from it.

Known issues:

- Search functionality can't split query into multiple terms due to MongoEngine query language limitations

For more, check the *mongoengine* API documentation.

2.7.3 Peewee

Features:

- Peewee 2.x+ support;
- Paging, sorting, filters, etc;
- Inline editing of related models;

In order to use peewee integration, you need to install two additional Python packages: peewee and wtf-peewee.

Known issues:

- Many-to-Many model relations are not supported: there's no built-in way to express M2M relation in Peewee

For more, check the *peewee* API documentation. Or look at the Peewee example at https://github.com/flask-admin/flask-admin/tree/master/examples/peewee.

2.7.4 PyMongo

The bare minimum you have to provide for Flask-Admin to work with PyMongo:

1. A list of columns by setting *column_list* property
2. Provide form to use by setting *form* property
3. When instantiating *flask_admin.contrib.pymongo.ModelView* class, you have to provide PyMongo collection object

This is minimal PyMongo view:

```python
class UserForm(Form):
    name = TextField('Name')
    email = TextField('Email')

class UserView(ModelView):
    column_list = ('name', 'email')
    form = UserForm

if __name__ == '__main__':
    admin = Admin(app)

    # 'db' is PyMongo database object
    admin.add_view(UserView(db['users']))
```

On top of that you can add sortable columns, filters, text search, etc.

For more, check the `pymongoe` API documentation. Or look at the Peewee example at https://github.com/flask-admin/flask-admin/tree/master/examples/pymongo.

2.8 Migrating From Django

If you are used to Django and the *django-admin* package, you will find Flask-Admin to work slightly different from what you would expect.

2.8.1 Design Philosophy

In general, Django and *django-admin* strives to make life easier by implementing sensible defaults. So a developer will be able to get an application up in no time, but it will have to conform to most of the defaults. Of course it is possible to customize things, but this often requires a good understanding of what's going on behind the scenes, and it can be rather tricky and time-consuming.

The design philosophy behind Flask is slightly different. It embraces the diversity that one tends to find in web applications by not forcing design decisions onto the developer. Rather than making it very easy to build an application that *almost* solves your whole problem, and then letting you figure out the last bit, Flask aims to make it possible for you to build the *whole* application. It might take a little more effort to get started, but once you've got the hang of it, the sky is the limit... Even when your application is a little different from most other applications out there on the web.

Flask-Admin follows this same design philosophy. So even though it provides you with several tools for getting up & running quickly, it will be up to you, as a developer, to tell Flask-Admin what should be displayed and how. Even though it is easy to get started with a simple CRUD interface for each model in your application, Flask-Admin doesn't fix you to this approach, and you are free to define other ways of interacting with some, or all, of your models.

Due to Flask-Admin supporting more than one ORM (SQLAlchemy, MongoEngine, Peewee, raw pymongo), the developer is even free to mix different model types into one application by instantiating appropriate CRUD classes.

Here is a list of some of the configuration properties that are made available by Flask-Admin and the SQLAlchemy backend. You can also see which *django-admin* properties they correspond to:

Django	Flask-Admin
actions	*actions*
exclude	*form_excluded_columns*
fields	*form_columns*
form	*form*
formfield_overrides	*form_args*
inlines	*inline_models*
list_display	*column_list*
list_filter	*column_filters*
list_per_page	*page_size*
search_fields	*column_searchable_list*
add_form_template	*create_template*
change_form_template	change_form_template

You might want to check *BaseModelView* for basic model configuration options (reused by all model backends) and specific backend documentation, for example *ModelView*. There's much more than what is displayed in this table.

2.9 Overriding The Form Scaffolding

If you don't want to the use the built-in Flask-Admin form scaffolding logic, you are free to roll your own by simply overriding `scaffold_form()`. For example, if you use WTForms-Alchemy, you could put your form generation code into a *scaffold_form* method in your *ModelView* class.

For SQLAlchemy, if the *synonym_property* does not return a SQLAlchemy field, then Flask-Admin won't be able to figure out what to do with it, so it won't generate a form field. In this case, you would need to manually contribute your own field:

```python
class MyView(ModelView):
    def scaffold_form(self):
        form_class = super(UserView, self).scaffold_form()
        form_class.extra = TextField('Extra')
        return form_class
```

2.10 Customizing Batch Actions

If you want to add other batch actions to the list view, besides the default delete action, then you can define a function that implements the desired logic and wrap it with the *@action* decorator.

The *action* decorator takes three parameters: *name*, *text* and *confirmation*. While the wrapped function should accept only one parameter - *ids*:

```python
from flask_admin.actions import action

class UserView(ModelView):
    @action('approve', 'Approve', 'Are you sure you want to approve selected users?')
    def action_approve(self, ids):
        try:
            query = User.query.filter(User.id.in_(ids))

            count = 0
            for user in query.all():
                if user.approve():
                    count += 1

            flash(ngettext('User was successfully approved.',
                           '%(count)s users were successfully approved.',
                           count,
                           count=count))
        except Exception as ex:
            if not self.handle_view_exception(ex):
                raise

            flash(gettext('Failed to approve users. %(error)s', error=str(ex)), 'error')
```

Adding A Model Backend

Flask-Admin makes a few assumptions about the database models that it works with. If you want to implement your own database backend, and still have Flask-Admin's model views work as expected, then you should take note of the following:

1. Each model must have one field which acts as a *primary key* to uniquely identify instances of that model. However, there are no restriction on the data type or the field name of the *primary key* field.

2. Models must make their data accessible as python properties.

If that is the case, then you can implement your own database backend by extending the *BaseModelView* class, and implementing the set of scaffolding methods listed below.

3.1 Extending BaseModelView

Start off by defining a new class, which derives from from *BaseModelView*:

```python
class MyDbModel(BaseModelView):
    pass
```

This class inherits BaseModelView's *__init__* method, which accepts a model class as first argument. The model class is stored as the attribute `self.model` so that other methods may access it.

Now, implement the following scaffolding methods for the new class:

1. *get_pk_value()*

   This method returns a primary key value from the model instance. In the SQLAlchemy backend, it gets the primary key from the model using *scaffold_pk()*, caches it and then returns the value from the model whenever requested.

   For example:

   ```python
   class MyDbModel(BaseModelView):
       def get_pk_value(self, model):
           return self.model.id
   ```

2. *scaffold_list_columns()*

   Returns a list of columns to be displayed in a list view. For example:

```python
class MyDbModel(BaseModelView):
    def scaffold_list_columns(self):
        columns = []

        for p in dir(self.model):
            attr = getattr(self.model)
            if isinstance(attr, MyDbColumn):
                columns.append(p)

        return columns
```

3. *scaffold_sortable_columns()*

    Returns a dictionary of sortable columns. The keys in the dictionary should correspond to the model's field names. The values should be those variables that will be used for sorting.

    For example, in the SQLAlchemy backend it is possible to sort by a foreign key field. So, if there is a field named *user*, which is a foreign key for the *Users* table, and the *Users* table also has a name field, then the key will be *user* and value will be *Users.name*.

    If your backend does not support sorting, return *None* or an empty dictionary.

4. *init_search()*

    Initialize search functionality. If your backend supports full-text search, do initializations and return *True*. If your backend does not support full-text search, return *False*.

    For example, SQLAlchemy backend reads value of the *self.searchable_columns* and verifies if all fields are of text type, if they're local to the current model (if not, it will add a join, etc) and caches this information for future use.

5. *scaffold_form()*

    Generate *WTForms* form class from the model.

    For example:

```python
class MyDbModel(BaseModelView):
    def scaffold_form(self):
        class MyForm(Form):
            pass

        # Do something
        return MyForm
```

6. *get_list()*

    This method should return list of model instances with paging, sorting, etc applied.

    For SQLAlchemy backend it looks like:

    (a) If search was enabled and provided search value is not empty, generate LIKE statements for each field from *self.searchable_columns*

    (b) If filter values were passed, call *apply* method with values:

```python
for flt, value in filters:
    query = self._filters[flt].apply(query, value)
```

    (c) Execute query to get total number of rows in the database (count)

(d) If *sort_column* was passed, will do something like (with some extra FK logic which is omitted in this example):

```python
if sort_desc:
    query = query.order_by(desc(sort_field))
else:
    query = query.order_by(sort_field)
```

(e) Apply paging

(f) Return count, list as a tuple

7. *get_one()*

   Return a model instance by its primary key.

8. *create_model()*

   Create a new instance of the model from the *Form* object.

9. *update_model()*

   Update the model instance with data from the form.

10. *delete_model()*

    Delete the specified model instance from the data store.

11. *is_valid_filter()*

    Verify whether the given object is a valid filter.

12. *scaffold_filters()*

    Return a list of filter objects for one model field.

    This method will be called once for each entry in the *self.column_filters* setting.

    If your backend does not know how to generate filters for the provided field, it should return *None*.

    For example:

```python
class MyDbModel(BaseModelView):
    def scaffold_filters(self, name):
        attr = getattr(self.model, name)

        if isinstance(attr, MyDbTextField):
            return [MyEqualFilter(name, name)]
```

3.2 Implementing filters

Each model backend should have its own set of filter implementations. It is not possible to use the filters from SQLAlchemy models in a non-SQLAlchemy backend. This also means that different backends might have different set of available filters.

The filter is a class derived from `BaseFilter` which implements at least two methods:

1. `apply()`

2. `operation()`

apply method accepts two parameters: *query* object and a value from the client. Here you can add filtering logic for the filter type.

Lets take SQLAlchemy model backend as an example:

All SQLAlchemy filters derive from `BaseSQLAFilter` class.

Each filter implements one simple filter SQL operation (like, not like, greater, etc) and accepts a column as input parameter.

Whenever model view wants to apply a filter to a query object, it will call *apply* method in a filter class with a query and value. Filter will then apply real filter operation.

For example:

```python
class MyBaseFilter(BaseFilter):
    def __init__(self, column, name, options=None, data_type=None):
        super(MyBaseFilter, self).__init__(name, options, data_type)

        self.column = column

class MyEqualFilter(MyBaseFilter):
    def apply(self, query, value):
        return query.filter(self.column == value)

    def operation(self):
        return gettext('equals')

    # You can validate values. If value is not valid,
    # return `False`, so filter will be ignored.
    def validate(self, value):
        return True

    # You can "clean" values before they will be
    # passed to the your data access layer
    def clean(self, value):
        return value
```

Feel free ask questions if you have problems adding a new model backend. Also, if you get stuck, try taking a look at the SQLAlchemy model backend and use it as a reference.

API

4.1 `flask_admin.base`

4.1.1 Base View

expose(*url='/'*, *methods=('GET',)*)

    Use this decorator to expose views in your view classes.

        Parameters

- **url** – Relative URL for the view
- **methods** – Allowed HTTP methods. By default only GET is allowed.

expose_plugview(*url='/'*)

    Decorator to expose Flask's pluggable view classes (`flask.views.View` or `flask.views.MethodView`).

        Parameters url – Relative URL for the view

    New in version 1.0.4.

class BaseView(*name=None*, *category=None*, *endpoint=None*, *url=None*, *static_folder=None*, *static_url_path=None*, *menu_class_name=None*, *menu_icon_type=None*, *menu_icon_value=None*)

    Base administrative view.

    Derive from this class to implement your administrative interface piece. For example:

```python
from flask_admin import BaseView, expose
class MyView(BaseView):
    @expose('/')
    def index(self):
        return 'Hello World!'
```

    Icons can be added to the menu by using *menu_icon_type* and *menu_icon_value*. For example:

```python
admin.add_view(MyView(name='My View', menu_icon_type='glyph', menu_icon_value='glyphicon-home'))
```

    create_blueprint(*admin*)

        Create Flask blueprint.

    get_url(*endpoint*, ***kwargs*)

        Generate URL for the endpoint. If you want to customize URL generation logic (persist some query string argument, for example), this is right place to do it.

> **Parameters**
>
> - **endpoint** – Flask endpoint name
> - **kwargs** – Arguments for *url_for*

inaccessible_callback(*name*, ***kwargs*)
> Handle the response to inaccessible views.
>
> By default, it throw HTTP 403 error. Override this method to customize the behaviour.

is_accessible()
> Override this method to add permission checks.
>
> Flask-Admin does not make any assumptions about the authentication system used in your application, so it is up to you to implement it.
>
> By default, it will allow access for everyone.

is_visible()
> Override this method if you want dynamically hide or show administrative views from Flask-Admin menu structure
>
> By default, item is visible in menu.
>
> Please note that item should be both visible and accessible to be displayed in menu.

render(*template*, ***kwargs*)
> Render template
>
> > **Parameters**
> >
> > - **template** – Template path to render
> > - **kwargs** – Template arguments

4.1.2 Default view

class **AdminIndexView**(*name=None*, *category=None*, *endpoint=None*, *url=None*, *template='admin/index.html'*, *menu_class_name=None*, *menu_icon_type=None*, *menu_icon_value=None*)
> Default administrative interface index page when visiting the /admin/ URL.

It can be overridden by passing your own view class to the Admin constructor:

```python
class MyHomeView(AdminIndexView):
    @expose('/')
    def index(self):
        arg1 = 'Hello'
        return self.render('admin/myhome.html', arg1=arg1)

admin = Admin(index_view=MyHomeView())
```

Also, you can change the root url from /admin to / with the following:

```python
admin = Admin(
    app,
    index_view=AdminIndexView(
        name='Home',
        template='admin/myhome.html',
        url='/'
    )
)
```

Default values for the index page are:

- •If a name is not provided, 'Home' will be used.

- •If an endpoint is not provided, will default to `admin`

- •Default URL route is `/admin`.

- •Automatically associates with static folder.

- •Default template is `admin/index.html`

4.1.3 Admin

class **Admin**(*app=None*, *name=None*, *url=None*, *subdomain=None*, *index_view=None*, *transla-
tions_path=None*, *endpoint=None*, *static_url_path=None*, *base_template=None*, *tem-
plate_mode=None*, *category_icon_classes=None*)
Collection of the admin views. Also manages menu structure.

add_link(*link*)
Add link to menu links collection.

Parameters **link** – Link to add.

add_links(**args*)
Add one or more links to the menu links collection.

Examples:

admin.add_links(link1) admin.add_links(link1, link2, link3, link4) admin.add_links(*my_list)

Parameters **args** – Argument list including the links to add.

add_view(*view*)
Add a view to the collection.

Parameters **view** – View to add.

add_views(**args*)
Add one or more views to the collection.

Examples:

admin.add_views(view1) admin.add_views(view1, view2, view3, view4) admin.add_views(*my_list)

Parameters **args** – Argument list including the views to add.

init_app(*app*)
Register all views with the Flask application.

Parameters **app** – Flask application instance

menu()
Return the menu hierarchy.

menu_links()
Return menu links.

4.2 flask_admin.helpers

get_current_view()
Get current administrative view.

Forms

`is_required_form_field`(*field*)
> Check if form field has *DataRequired* or *InputRequired* validators.

> > **Parameters field** – WTForms field to check

`is_form_submitted`()
> Check if current method is PUT or POST

`validate_form_on_submit`(*form*)
> If current method is PUT or POST, validate form and return validation status.

`get_form_data`()
> If current method is PUT or POST, return concatenated *request.form* with *request.files* or *None* otherwise.

`is_field_error`(*errors*)
> Check if wtforms field has error without checking its children.

> > **Parameters errors** – Errors list.

Jinja2 helpers

`resolve_ctx`(*context*)
> Resolve current Jinja2 context and store it for general consumption.

`get_render_ctx`()
> Get view template context.

4.3 `flask_admin.model`

class `BaseModelView`(*model*, *name=None*, *category=None*, *endpoint=None*, *url=None*, *static_folder=None*, *menu_class_name=None*, *menu_icon_type=None*, *menu_icon_value=None*)
> Base model view.

> This view does not make any assumptions on how models are stored or managed, but expects the following:

> > 1. The provided model is an object

> > 2. The model contains properties

> > 3. Each model contains an attribute which uniquely identifies it (i.e. a primary key for a database model)

> > 4. It is possible to retrieve a list of sorted models with pagination applied from a data source

> > 5. You can get one model by its identifier from the data source

> Essentially, if you want to support a new data store, all you have to do is:

> > 1. Derive from the *BaseModelView* class

> > 2. Implement various data-related methods (*get_list*, *get_one*, *create_model*, etc)

> > 3. Implement automatic form generation from the model representation (*scaffold_form*)

> **`can_create`** = **True**
> > Is model creation allowed

> **`can_edit`** = **True**
> > Is model editing allowed

> **`can_delete`** = **True**
> > Is model deletion allowed

---

list_template = 'admin/model/list.html'
> Default list view template

edit_template = 'admin/model/edit.html'
> Default edit template

create_template = 'admin/model/create.html'
> Default create template

column_list
> Collection of the model field names for the list view. If set to *None*, will get them from the model.
>
> For example:

```python
class MyModelView(BaseModelView):
    column_list = ('name', 'last_name', 'email')
```

column_exclude_list
> Collection of excluded list column names.
>
> For example:

```python
class MyModelView(BaseModelView):
    column_exclude_list = ('last_name', 'email')
```

column_labels
> Dictionary where key is column name and value is string to display.
>
> For example:

```python
class MyModelView(BaseModelView):
    column_labels = dict(name='Name', last_name='Last Name')
```

column_descriptions = None
> Dictionary where key is column name and value is description for *list view* column or add/edit form field.
>
> For example:

```python
class MyModelView(BaseModelView):
    column_descriptions = dict(
        full_name='First and Last name'
    )
```

column_formatters
> Dictionary of list view column formatters.
>
> For example, if you want to show price multiplied by two, you can do something like this:

```python
class MyModelView(BaseModelView):
    column_formatters = dict(price=lambda v, c, m, p: m.price*2)
```

> or using Jinja2 *macro* in template:

```python
from flask_admin.model.template import macro

class MyModelView(BaseModelView):
    column_formatters = dict(price=macro('render_price'))

# in template
{% macro render_price(model, column) %}
    {{ model.price * 2 }}
{% endmacro %}
```

The Callback function has the prototype:

```python
def formatter(view, context, model, name):
    # `view` is current administrative view
    # `context` is instance of jinja2.runtime.Context
    # `model` is model instance
    # `name` is property name
    pass
```

column_type_formatters

Dictionary of value type formatters to be used in the list view.

By default, two types are formatted:

1. None will be displayed as an empty string

2. bool will be displayed as a checkmark if it is True

If you don't like the default behavior and don't want any type formatters applied, just override this property with an empty dictionary:

```python
class MyModelView(BaseModelView):
    column_type_formatters = dict()
```

If you want to display *NULL* instead of an empty string, you can do something like this. Also comes with bonus *date* formatter:

```python
from datetime import date
from flask_admin.model import typefmt

def date_format(view, value):
    return value.strftime('%d.%m.%Y')

MY_DEFAULT_FORMATTERS = dict(typefmt.BASE_FORMATTERS)
MY_DEFAULT_FORMATTERS.update({
        type(None): typefmt.null_formatter,
        date: date_format
    })

class MyModelView(BaseModelView):
    column_type_formatters = MY_DEFAULT_FORMATTERS
```

Type formatters have lower priority than list column formatters.

The callback function has following prototype:

```python
def type_formatter(view, value):
    # `view` is current administrative view
    # `value` value to format
    pass
```

column_display_pk

Controls if the primary key should be displayed in the list view.

column_sortable_list

Collection of the sortable columns for the list view. If set to *None*, will get them from the model.

For example:

```python
class MyModelView(BaseModelView):
    column_sortable_list = ('name', 'last_name')
```

If you want to explicitly specify field/column to be used while sorting, you can use a tuple:

```python
class MyModelView(BaseModelView):
    column_sortable_list = ('name', ('user', 'user.username'))
```

When using SQLAlchemy models, model attributes can be used instead of strings:

```python
class MyModelView(BaseModelView):
    column_sortable_list = ('name', ('user', User.username))
```

column_searchable_list

A collection of the searchable columns. It is assumed that only text-only fields are searchable, but it is up to the model implementation to decide.

Example:

```python
class MyModelView(BaseModelView):
    column_searchable_list = ('name', 'email')
```

column_default_sort = None

Default sort column if no sorting is applied.

Example:

```python
class MyModelView(BaseModelView):
    column_default_sort = 'user'
```

You can use tuple to control ascending descending order. In following example, items will be sorted in descending order:

```python
class MyModelView(BaseModelView):
    column_default_sort = ('user', True)
```

column_choices = None

Map choices to columns in list view

Example:

```python
class MyModelView(BaseModelView):
    column_choices = {
        'my_column': [
            ('db_value', 'display_value'),
        ]
    }
```

column_filters = None

Collection of the column filters.

Can contain either field names or instances of `BaseFilter` classes.

Example:

```python
class MyModelView(BaseModelView):
    column_filters = ('user', 'email')
```

form = None

Form class. Override if you want to use custom form for your model. Will completely disable form scaffolding functionality.

For example:

```
class MyForm(Form):
    name = StringField('Name')

class MyModelView(BaseModelView):
    form = MyForm
```

form_base_class = <class 'flask_admin.form.BaseForm'>
Base form class. Will be used by form scaffolding function when creating model form.

Useful if you want to have custom contructor or override some fields.

Example:

```
class MyBaseForm(Form):
    def do_something(self):
        pass

class MyModelView(BaseModelView):
    form_base_class = MyBaseForm
```

form_columns = None
Collection of the model field names for the form. If set to *None* will get them from the model.

Example:

```
class MyModelView(BaseModelView):
    form_columns = ('name', 'email')
```

form_excluded_columns
Collection of excluded form field names.

For example:

```
class MyModelView(BaseModelView):
    form_excluded_columns = ('last_name', 'email')
```

form_args = None
Dictionary of form field arguments. Refer to WTForms documentation for list of possible options.

Example:

```
from wtforms.validators import required
class MyModelView(BaseModelView):
    form_args = dict(
        name=dict(label='First Name', validators=[required()])
    )
```

form_overrides = None
Dictionary of form column overrides.

Example:

```
class MyModelView(BaseModelView):
    form_overrides = dict(name=wtf.FileField)
```

form_widget_args = None
Dictionary of form widget rendering arguments. Use this to customize how widget is rendered without using custom template.

Example:

```
class MyModelView(BaseModelView):
    form_widget_args = {
        'description': {
            'rows': 10,
            'style': 'color: black'
        }
    }
```

Changing the format of a DateTimeField will require changes to both form_widget_args and form_args.

Example:

```
form_args = dict(
    start=dict(format='%Y-%m-%d %I:%M %p') # changes how the input is parsed by strptime (12
)
form_widget_args = dict(
    start={'data-date-format': u'yyyy-mm-dd HH:ii P', 'data-show-meridian': 'True'} # change
)
```

form_extra_fields = None
    Dictionary of additional fields.

    Example:

```
class MyModelView(BaseModelView):
    form_extra_fields = {
        'password': PasswordField('Password')
    }
```

You can control order of form fields using `form_columns` property. For example:

```
class MyModelView(BaseModelView):
    form_columns = ('name', 'email', 'password', 'secret')

    form_extra_fields = {
        'password': PasswordField('Password')
    }
```

In this case, password field will be put between email and secret fields that are autogenerated.

form_ajax_refs = None
    Use AJAX for foreign key model loading.

    Should contain dictionary, where key is field name and value is either a dictionary which configures AJAX lookups or backend-specific *AjaxModelLoader* class instance.

    For example, it can look like:

```
class MyModelView(BaseModelView):
    form_ajax_refs = {
        'user': {
            'fields': ('first_name', 'last_name', 'email'),
            'page_size': 10
        }
    }
```

Or with SQLAlchemy backend like this:

```
class MyModelView(BaseModelView):
    form_ajax_refs = {
```

```
            'user': QueryAjaxModelLoader('user', db.session, User, fields=['email'], page_size=1
        }
```

> If you need custom loading functionality, you can implement your custom loading behavior in your *Ajax-ModelLoader* class.

form_create_rules = None
> Customized rules for the create form. Override *form_rules* if present.

form_edit_rules = None
> Customized rules for the edit form. Override *form_rules* if present.

action_disallowed_list
> Set of disallowed action names. For example, if you want to disable mass model deletion, do something like this:
>
> > **class MyModelView(BaseModelView):** action_disallowed_list = ['delete']

page_size = 20
> Default page size for pagination.

action_view(**args*, ***kwargs*)
> Mass-model action view.

after_model_change(*form*, *model*, *is_created*)
> Perform some actions after a model was created or updated and committed to the database.
>
> Called from create_model after successful database commit.
>
> By default does nothing.
>
> > **Parameters**
> >
> > - **form** – Form used to create/update model
> >
> > - **model** – Model that was created/updated
> >
> > - **is_created** – True if model was created, False if model was updated

after_model_delete(*model*)
> Perform some actions after a model was deleted and committed to the database.
>
> Called from delete_model after successful database commit (if it has any meaning for a store backend).
>
> By default does nothing.
>
> > **Parameters model** – Model that was deleted

ajax_update(**args*, ***kwargs*)
> Edits a single column of a record in list view.

can_view_details = False
> Setting this to true will enable the details view. This is recommended when there are too many columns to display in the list_view.

column_details_exclude_list = None
> Collection of fields excluded from the details view.

column_details_list = None
> Collection of the field names included in the details view. If set to *None*, will get them from the model.

column_editable_list = None
> Collection of the columns which can be edited from the list view.
>
> For example:

```
class MyModelView(BaseModelView):
    column_editable_list = ('name', 'last_name')
```

create_form(*obj=None*)
> Instantiate model creation form and return it.
>
> Override to implement custom behavior.

create_modal = False
> Setting this to true will display the create_view as a modal dialog.

create_modal_template = 'admin/model/modals/create.html'
> Default create modal template

create_model(*form*)
> Create model from the form.
>
> Returns the model instance if operation succeeded.
>
> Must be implemented in the child class.
>
> > **Parameters** **form** – Form instance

create_view(**args*, ***kwargs*)
> Create model view

delete_form()
> Instantiate model delete form and return it.
>
> Override to implement custom behavior.
>
> The delete form originally used a GET request, so delete_form accepts both GET and POST request for backwards compatibility.

delete_model(*model*)
> Delete model.
>
> Returns *True* if operation succeeded.
>
> Must be implemented in the child class.
>
> > **Parameters** **model** – Model instance

delete_view(**args*, ***kwargs*)
> Delete model view. Only POST method is allowed.

details_modal = False
> Setting this to true will display the details_view as a modal dialog.

details_modal_template = 'admin/model/modals/details.html'
> Default details modal view template

details_template = 'admin/model/details.html'
> Default details view template

details_view(**args*, ***kwargs*)
> Details model view

edit_form(*obj=None*)
> Instantiate model editing form and return it.
>
> Override to implement custom behavior.

edit_modal = False
> Setting this to true will display the edit_view as a modal dialog.

---

edit_modal_template = 'admin/model/modals/edit.html'
> Default edit modal template

edit_view(**args*, ***kwargs*)
> Edit model view

form_rules = None
> List of rendering rules for model creation form.
>
> This property changed default form rendering behavior and makes possible to rearrange order of rendered fields, add some text between fields, group them, etc. If not set, will use default Flask-Admin form rendering logic.
>
> Here's simple example which illustrates how to use:

```python
from flask_admin.form import rules

class MyModelView(ModelView):
    form_rules = [
        # Define field set with header text and four fields
        rules.FieldSet(('first_name', 'last_name', 'email', 'phone'), 'User'),
        # ... and it is just shortcut for:
        rules.Header('User'),
        rules.Field('first_name'),
        rules.Field('last_name'),
        # ...
        # It is possible to create custom rule blocks:
        MyBlock('Hello World'),
        # It is possible to call macros from current context
        rules.Macro('my_macro', foobar='baz')
    ]
```

get_column_name(*field*)
> Return a human-readable column name.
>
> > **Parameters field** – Model field name.

get_create_form()
> Create form class for model creation view.
>
> Override to implement customized behavior.

get_delete_form()
> Create form class for model delete view.
>
> Override to implement customized behavior.

get_details_columns()
> Returns a list of the model field names in the details view. If *column_details_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

get_edit_form()
> Create form class for model editing view.
>
> Override to implement customized behavior.

get_filter_arg(*index*, *flt*)
> Given a filter *flt*, return a unique name for that filter in this view.
>
> Does not include the *flt[n]_* portion of the filter name.
>
> > **Parameters**
> >
> > • **index** – Filter index in _filters array

- **flt** – Filter instance

get_filters()
>   Return a list of filter objects.

>   If your model backend implementation does not support filters, override this method and return *None*.

get_form()
>   Get form class.

>   If self.form is set, will return it and will call self.scaffold_form otherwise.

>   Override to implement customized behavior.

get_list(*page*, *sort_field*, *sort_desc*, *search*, *filters*)
>   Return a paginated and sorted list of models from the data source.

>   Must be implemented in the child class.

>   > **Parameters**

>   > - **page** – Page number, 0 based. Can be set to None if it is first page.
>   > - **sort_field** – Sort column name or None.
>   > - **sort_desc** – If set to True, sorting is in descending order.
>   > - **search** – Search query
>   > - **filters** – List of filter tuples. First value in a tuple is a search index, second value is a search value.

get_list_columns()
>   Returns a list of the model field names. If *column_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

get_list_form()
>   Get form class for the editable list view.

>   Uses only validators from *form_args* to build the form class.

>   Allows overriding the editable list view field/widget. For example:

```python
from flask_admin.model.fields import ListEditableFieldList
from flask_admin.model.widgets import XEditableWidget

class CustomWidget(XEditableWidget):
    def get_kwargs(self, subfield, kwargs):
        if subfield.type == 'TextAreaField':
            kwargs['data-type'] = 'textarea'
            kwargs['data-rows'] = '20'
        # elif: kwargs for other fields

        return kwargs

class CustomFieldList(ListEditableFieldList):
    widget = CustomWidget()

class MyModelView(BaseModelView):
    def get_list_form(self):
        return self.scaffold_list_form(CustomFieldList)
```

get_list_value(*context*, *model*, *name*)
>   Returns the value to be displayed in the list view

> **Parameters**
>
> - **context** – jinja2.runtime.Context
>
> - **model** – Model instance
>
> - **name** – Field name

get_one(*id*)

> Return one model by its id.
>
> Must be implemented in the child class.
>
> > **Parameters id** – Model id

get_pk_value(*model*)

> Return PK value from a model object.

get_save_return_url(*model*, *is_created=False*)

> Return url where user is redirected after successful form save.
>
> > **Parameters**
> >
> > - **model** – Saved object
> >
> > - **is_created** – Whether new object was created or existing one was updated
>
> For example, redirect use to object details view after form save:

```python
class MyModelView(ModelView):
    can_view_details = True

    def get_save_return_url(self, model, is_created):
        return self.get_url('.details_view', id=model.id)
```

get_sortable_columns()

> Returns a dictionary of the sortable columns. Key is a model field name and value is sort column (for example - attribute).
>
> If *column_sortable_list* is set, will use it. Otherwise, will call *scaffold_sortable_columns* to get them from the model.

handle_filter(*filter*)

> Postprocess (add joins, etc) for a filter.
>
> > **Parameters filter** – Filter object to postprocess

index_view(**args*, ***kwargs*)

> List view

init_search()

> Initialize search. If data provider does not support search, *init_search* will return *False*.

is_action_allowed(*name*)

> Override this method to allow or disallow actions based on some condition.
>
> The default implementation only checks if the particular action is not in *action_disallowed_list*.

is_editable(*name*)

> Verify if column is editable.
>
> > **Parameters name** – Column name.

is_sortable(*name*)

> Verify if column is sortable.

Not case-sensitive.

> **Parameters** **name** – Column name.

is_valid_filter(*filter*)
Verify that the provided filter object is valid.

Override in model backend implementation to verify if the provided filter type is allowed.

> **Parameters** **filter** – Filter object to verify.

list_form(*obj=None*)
Instantiate model editing form for list view and return it.

Override to implement custom behavior.

named_filter_urls = False
Set to True to use human-readable names for filters in URL parameters.

False by default so as to be robust across translations.

Changing this parameter will break any existing URLs that have filters.

on_form_prefill(*form*, *id*)
Perform additional actions to pre-fill the edit form.

Called from edit_view, if the current action is rendering the form rather than receiving client side input, after default pre-filling has been performed.

By default does nothing.

You only need to override this if you have added custom fields that depend on the database contents in a way that Flask-admin can't figure out by itself. Fields that were added by name of a normal column or relationship should work out of the box.

> **Parameters**
>
> - **form** – Form instance
>
> - **id** – id of the object that is going to be edited

on_model_change(*form*, *model*, *is_created*)
Perform some actions after a model is created or updated.

Called from create_model and update_model in the same transaction (if it has any meaning for a store backend).

By default does nothing.

> **Parameters**
>
> - **form** – Form used to create/update model
>
> - **model** – Model that will be created/updated
>
> - **is_created** – Will be set to True if model was created and to False if edited

on_model_delete(*model*)
Perform some actions before a model is deleted.

Called from delete_model in the same transaction (if it has any meaning for a store backend).

By default do nothing.

scaffold_filters(*name*)
Generate filter object for the given name

> **Parameters** **name** – Name of the field

---

scaffold_form()
> Create *form.BaseForm* inherited class from the model. Must be implemented in the child class.

scaffold_list_columns()
> Return list of the model field names. Must be implemented in the child class.
>
> Expected return format is list of tuples with field name and display text. For example:

```
['name', 'first_name', 'last_name']
```

scaffold_list_form(*custom_fieldlist=<class   'flask_admin.model.fields.ListEditableFieldList'>*, *validators=None*)
> Create form for the *index_view* using only the columns from *self.column_editable_list*.
>
> > **Parameters**
> >
> > - **validators** – *form_args* dict with only validators {'name': {'validators': [required()]}}
> >
> > - **custom_fieldlist** – A WTForm FieldList class. By default, *ListEditableFieldList*.
>
> Must be implemented in the child class.

scaffold_sortable_columns()
> Returns dictionary of sortable columns. Must be implemented in the child class.
>
> Expected return format is a dictionary, where keys are field names and values are property names.

simple_list_pager = **False**
> Enable or disable simple list pager. If enabled, model interface would not run count query and will only show prev/next pager buttons.

update_model(*form*, *model*)
> Update model from the form.
>
> Returns *True* if operation succeeded.
>
> Must be implemented in the child class.
>
> > **Parameters**
> >
> > - **form** – Form instance
> >
> > - **model** – Model instance

validate_form(*form*)
> Validate the form on submit.
>
> > **Parameters form** – Form to validate

4.4 `flask_admin.form`

class **BaseForm**(*formdata=None*, *obj=None*, *prefix=u''*, ***kwargs*)

4.5 `flask_admin.form.rules`

class **BaseRule**
> Base form rule. All form formatting rules should derive from *BaseRule*.

class **NestedRule** (*rules=[]*, *separator=''*)

> Nested rule. Can contain child rules and render them.

> **__init__** (*rules=[]*, *separator=''*)
> > Constructor.

> > > **Parameters**

> > > > • **rules** – Child rule list

> > > > • **separator** – Default separator between rules when rendering them.

class **Text** (*text*, *escape=True*)

> Render text (or HTML snippet) from string.

> **__init__** (*text*, *escape=True*)
> > Constructor.

> > > **Parameters**

> > > > • **text** – Text to render

> > > > • **escape** – Should text be escaped or not. Default is *True*.

class **HTML** (*html*)

> Shortcut for *Text* rule with *escape* set to *False*.

class **Macro** (*macro_name*, ***kwargs*)

> Render macro by its name from current Jinja2 context.

> **__init__** (*macro_name*, ***kwargs*)
> > Constructor.

> > > **Parameters**

> > > > • **macro_name** – Macro name

> > > > • **kwargs** – Default macro parameters

class **Container** (*macro_name*, *child_rule*, ***kwargs*)

> Render container around child rule.

> **__init__** (*macro_name*, *child_rule*, ***kwargs*)
> > Constructor.

> > > **Parameters**

> > > > • **macro_name** – Macro name that will be used as a container

> > > > • **child_rule** – Child rule to be rendered inside of container

> > > > • **kwargs** – Container macro arguments

class **Field** (*field_name*, *render_field='lib.render_field'*)

> Form field rule.

> **__init__** (*field_name*, *render_field='lib.render_field'*)
> > Constructor.

> > > **Parameters**

> > > > • **field_name** – Field name to render

> > > > • **render_field** – Macro that will be used to render the field.

class **Header** (*text*, *header_macro='lib.render_header'*)

> Render header text.

__init__ (*text*, *header_macro='lib.render_header'*)

Constructor.

> **Parameters**
>
> - **text** – Text to render
>
> - **header_macro** – Header rendering macro

class **FieldSet** (*rules*, *header=None*, *separator=''*)

Field set with header.

__init__ (*rules*, *header=None*, *separator=''*)

Constructor.

> **Parameters**
>
> - **rules** – Child rules
>
> - **header** – Header text
>
> - **separator** – Child rule separator

4.6 `flask_admin.form.fields`

class **TimeField** (*label=None*, *validators=None*, *formats=None*, *default_format=None*, *widget_format=None*, ***kwargs*)

A text field which stores a *datetime.time* object. Accepts time string in multiple formats: 20:10, 20:10:00, 10:00 am, 9:30pm, etc.

class **Select2Field** (*label=None*, *validators=None*, *coerce=<type 'unicode'>*, *choices=None*, *allow_blank=False*, *blank_text=None*, ***kwargs*)

Select2 styled select widget.

You must include select2.js, form-x.x.x.js and select2 stylesheet for it to work.

class **Select2TagsField** (*label=None*, *validators=None*, *save_as_list=False*, *coerce=<type 'unicode'>*, ***kwargs*)

Select2 styled text field. You must include select2.js, form-x.x.x.js and select2 stylesheet for it to work.

4.7 `flask_admin.form.upload`

class **FileUploadField** (*label=None*, *validators=None*, *base_path=None*, *relative_path=None*, *namegen=None*, *allowed_extensions=None*, *permission=438*, *allow_overwrite=True*, ***kwargs*)

Customizable file-upload field.

Saves file to configured path, handles updates and deletions. Inherits from *StringField*, resulting filename will be stored as string.

__init__ (*label=None*, *validators=None*, *base_path=None*, *relative_path=None*, *namegen=None*, *allowed_extensions=None*, *permission=438*, *allow_overwrite=True*, ***kwargs*)

Constructor.

> **Parameters**
>
> - **label** – Display label
>
> - **validators** – Validators

- **base_path** – Absolute path to the directory which will store files

- **relative_path** – Relative path from the directory. Will be prepended to the file name for uploaded files. Flask-Admin uses *urlparse.urljoin* to generate resulting filename, so make sure you have trailing slash.

- **namegen** – Function that will generate filename from the model and uploaded file object. Please note, that model is "dirty" model object, before it was committed to database.

    For example:

```python
import os.path as op

def prefix_name(obj, file_data):
    parts = op.splitext(file_data.filename)
    return secure_filename('file-%s%s' % parts)

class MyForm(BaseForm):
    upload = FileUploadField('File', namegen=prefix_name)
```

- **allowed_extensions** – List of allowed extensions. If not provided, will allow any file.

- **allow_overwrite** – Whether to overwrite existing files in upload directory. Defaults to *True*.

New in version 1.1.1: The *allow_overwrite* parameter was added.

class ImageUploadField(*label=None*, *validators=None*, *base_path=None*, *relative_path=None*, *namegen=None*, *allowed_extensions=None*, *max_size=None*, *thumbgen=None*, *thumbnail_size=None*, *permission=438*, *url_relative_path=None*, *endpoint='static'*, ***kwargs*)

Image upload field.

Does image validation, thumbnail generation, updating and deleting images.

Requires PIL (or Pillow) to be installed.

__init__(*label=None*, *validators=None*, *base_path=None*, *relative_path=None*, *namegen=None*, *allowed_extensions=None*, *max_size=None*, *thumbgen=None*, *thumbnail_size=None*, *permission=438*, *url_relative_path=None*, *endpoint='static'*, ***kwargs*)

Constructor.

Parameters

- **label** – Display label

- **validators** – Validators

- **base_path** – Absolute path to the directory which will store files

- **relative_path** – Relative path from the directory. Will be prepended to the file name for uploaded files. Flask-Admin uses *urlparse.urljoin* to generate resulting filename, so make sure you have trailing slash.

- **namegen** – Function that will generate filename from the model and uploaded file object. Please note, that model is "dirty" model object, before it was committed to database.

    For example:

```python
import os.path as op

def prefix_name(obj, file_data):
```

```
        parts = op.splitext(file_data.filename)
        return secure_filename('file-%s%s' % parts)

class MyForm(BaseForm):
    upload = FileUploadField('File', namegen=prefix_name)
```

- **allowed_extensions** – List of allowed extensions. If not provided, then gif, jpg, jpeg, png and tiff will be allowed.

- **max_size** – Tuple of (width, height, force) or None. If provided, Flask-Admin will resize image to the desired size.

  Width and height is in pixels. If *force* is set to *True*, will try to fit image into dimensions and keep aspect ratio, otherwise will just resize to target size.

- **thumbgen** – Thumbnail filename generation function. All thumbnails will be saved as JPEG files, so there's no need to keep original file extension.

  For example:

```
import os.path as op

def thumb_name(filename):
    name, _ = op.splitext(filename)
    return secure_filename('%s-thumb.jpg' % name)

class MyForm(BaseForm):
    upload = ImageUploadField('File', thumbgen=prefix_name)
```

- **thumbnail_size** – Tuple or (width, height, force) values. If not provided, thumbnail won't be created.

  Width and height is in pixels. If *force* is set to *True*, will try to fit image into dimensions and keep aspect ratio, otherwise will just resize to target size.

- **url_relative_path** – Relative path from the root of the static directory URL. Only gets used when generating preview image URLs.

  For example, your model might store just file names (*relative_path* set to *None*), but *base_path* is pointing to subdirectory.

- **endpoint** – Static endpoint for images. Used by widget to display previews. Defaults to 'static'.

class **FileUploadInput**
> Renders a file input chooser field.
>
> You can customize *empty_template* and *data_template* members to customize look and feel.

class **ImageUploadInput**
> Renders a image input chooser field.
>
> You can customize *empty_template* and *data_template* members to customize look and feel.

4.8 flask_admin.tools

import_module(*name*, *required=True*)
> Import module by name

> **Parameters**

- **name** – Module name

- **required** – If set to *True* and module was not found - will throw exception. If set to *False* and module was not found - will return None. Default is *True*.

import_attribute(*name*)

Import attribute using string reference.

> **Parameters name** – String reference.

Raises ImportError or AttributeError if module or attribute do not exist.

Example:

```
import_attribute('a.b.c.foo')
```

module_not_found(*additional_depth=0*)

Checks if ImportError was raised because module does not exist or something inside it raised ImportError

> **Parameters additional_depth** – supply int of depth of your call if you're not doing import on the same level of code - f.e., if you call function, which is doing import, you should pass 1 for single additional level of depth

rec_getattr(*obj*, *attr*, *default=None*)

Recursive getattr.

> **Parameters**
>
> - **attr** – Dot delimited attribute name
>
> - **default** – Default value

Example:

```
rec_getattr(obj, 'a.b.c')
```

4.9 `flask_admin.actions`

action(*name*, *text*, *confirmation=None*)

Use this decorator to expose actions that span more than one entity (model, file, etc)

> **Parameters**
>
> - **name** – Action name
>
> - **text** – Action text.
>
> - **confirmation** – Confirmation text. If not provided, action will be executed unconditionally.

class **ActionsMixin**

Actions mixin.

In some cases, you might work with more than one "entity" (model, file, etc) in your admin view and will want to perform actions on a group of entities simultaneously.

In this case, you can add this functionality by doing this: 1. Add this mixin to your administrative view class 2. Call *init_actions* in your class constructor 3. Expose actions view 4. Import *actions.html* library and add call library macros in your template

get_actions_list()

Return a list and a dictionary of allowed actions.

handle_action(*return_view=None*)
> Handle action request.

>> Parameters **return_view** – Name of the view to return to after the request. If not provided, will return user to the return url in the form or the list view.

init_actions()
> Initialize list of actions for the current administrative view.

is_action_allowed(*name*)
> Verify if action with *name* is allowed.

>> Parameters **name** – Action name

4.10 `flask_admin.contrib.sqla`

SQLAlchemy model backend implementation.

class **ModelView**(*model, session, name=None, category=None, endpoint=None, url=None, static_folder=None, menu_class_name=None, menu_icon_type=None, menu_icon_value=None*)
> SQLAlchemy model view

> Usage sample:

```
admin = Admin()
admin.add_view(ModelView(User, db.session))
```

> Class inherits configuration options from *BaseModelView* and they're not displayed here.

> **column_auto_select_related**
>> Enable automatic detection of displayed foreign keys in this view and perform automatic joined loading for related models to improve query performance.

>> Please note that detection is not recursive: if *__unicode__* method of related model uses another model to generate string representation, it will still make separate database call.

> **column_select_related_list**
>> List of parameters for SQLAlchemy *subqueryload*. Overrides *column_auto_select_related* property.

>> For example:

```
class PostAdmin(ModelView):
    column_select_related_list = ('user', 'city')
```

>> You can also use properties:

```
class PostAdmin(ModelView):
    column_select_related_list = (Post.user, Post.city)
```

>> Please refer to the *subqueryload* on list of possible values.

> **column_searchable_list**
>> Collection of the searchable columns.

>> Example:

```
class MyModelView(ModelView):
    column_searchable_list = ('name', 'email')
```

>> You can also pass columns:

```
class MyModelView(ModelView):
    column_searchable_list = (User.name, User.email)
```

The following search rules apply:

•If you enter `ZZZ` in the UI search field, it will generate `ILIKE '%ZZZ%'` statement against searchable columns.

•If you enter multiple words, each word will be searched separately, but only rows that contain all words will be displayed. For example, searching for `abc def` will find all rows that contain `abc` and `def` in one or more columns.

•If you prefix your search term with ^, it will find all rows that start with ^. So, if you entered `^ZZZ` then `ILIKE 'ZZZ%'` will be used.

•If you prefix your search term with =, it will perform an exact match. For example, if you entered `=ZZZ`, the statement `ILIKE 'ZZZ'` will be used.

column_filters = None
Collection of the column filters.

Can contain either field names or instances of `flask_admin.contrib.sqla.filters.BaseFilter` classes.

For example:

```
class MyModelView(BaseModelView):
    column_filters = ('user', 'email')
```

or:

```
class MyModelView(BaseModelView):
    column_filters = (BooleanEqualFilter(User.name, 'Name'))
```

filter_converter = <flask_admin.contrib.sqla.filters.FilterConverter object>
Field to filter converter.

Override this attribute to use non-default converter.

model_form_converter = <class 'flask_admin.contrib.sqla.form.AdminModelConverter'>
Model form conversion class. Use this to implement custom field conversion logic.

For example:

```
class MyModelConverter(AdminModelConverter):
    pass

class MyAdminView(ModelView):
    model_form_converter = MyModelConverter
```

inline_model_form_converter = <class 'flask_admin.contrib.sqla.form.InlineModelConverter'>
Inline model conversion class. If you need some kind of post-processing for inline forms, you can customize behavior by doing something like this:

```
class MyInlineModelConverter(InlineModelConverter):
    def post_process(self, form_class, info):
        form_class.value = wtf.StringField('value')
        return form_class

class MyAdminView(ModelView):
    inline_model_form_converter = MyInlineModelConverter
```

---

fast_mass_delete = False

> If set to *False* and user deletes more than one model using built in action, all models will be read from the database and then deleted one by one giving SQLAlchemy a chance to manually cleanup any dependencies (many-to-many relationships, etc).
>
> If set to *True*, will run a DELETE statement which is somewhat faster, but may leave corrupted data if you forget to configure DELETE CASCADE for your model.

inline_models = None

> Inline related-model editing for models with parent-child relations.
>
> Accepts enumerable with one of the following possible values:
>
> > 1. Child model class:

```python
class MyModelView(ModelView):
    inline_models = (Post,)
```

> > 2. Child model class and additional options:

```python
class MyModelView(ModelView):
    inline_models = [(Post, dict(form_columns=['title']))]
```

> > 3. Django-like InlineFormAdmin class instance:

```python
class MyInlineModelForm(InlineFormAdmin):
    form_columns = ('title', 'date')

class MyModelView(ModelView):
    inline_models = (MyInlineModelForm(MyInlineModel),)
```

> You can customize the generated field name by:
>
> > 1. Using the *form_name* property as a key to the options dictionary:

```python
class MyModelView(ModelView):
    inline_models = ((Post, dict(form_label='Hello')))
```

> > 2. Using forward relation name and *column_labels* property:

```python
class Model1(Base):
    pass

class Model2(Base):
    # ...
    model1 = relation(Model1, backref='models')

class MyModel1View(Base):
    inline_models = (Model2,)
    column_labels = {'models': 'Hello'}
```

form_choices = None

> Map choices to form fields
>
> Example:

```
class MyModelView(BaseModelView):
    form_choices = {'my_form_field': [
        ('db_value', 'display_value'),
    ]}
```

form_optional_types = (<class 'sqlalchemy.sql.sqltypes.Boolean'>,)
 List of field types that should be optional if column is not nullable.

 Example:

```
class MyModelView(BaseModelView):
    form_optional_types = (Boolean, Unicode)
```

action_view(*args*, ***kwargs*)
 Mass-model action view.

after_model_change(*form*, *model*, *is_created*)
 Perform some actions after a model was created or updated and committed to the database.

 Called from create_model after successful database commit.

 By default does nothing.

> **Parameters**
>> • **form** – Form used to create/update model
>>
>> • **model** – Model that was created/updated
>>
>> • **is_created** – True if model was created, False if model was updated

after_model_delete(*model*)
 Perform some actions after a model was deleted and committed to the database.

 Called from delete_model after successful database commit (if it has any meaning for a store backend).

 By default does nothing.

> **Parameters model** – Model that was deleted

ajax_update(*args*, ***kwargs*)
 Edits a single column of a record in list view.

column_display_all_relations
 Controls if list view should display all relations, not only many-to-one.

create_blueprint(*admin*)
 Create Flask blueprint.

create_form(*obj=None*)
 Instantiate model creation form and return it.

 Override to implement custom behavior.

create_model(*form*)
 Create model from form.

> **Parameters form** – Form instance

create_view(*args*, ***kwargs*)
 Create model view

delete_form()
 Instantiate model delete form and return it.

 Override to implement custom behavior.

The delete form originally used a GET request, so delete_form accepts both GET and POST request for backwards compatibility.

delete_model(*model*)
    Delete model.

> **Parameters model** – Model to delete

delete_view(**args*, ***kwargs*)
    Delete model view. Only POST method is allowed.

details_view(**args*, ***kwargs*)
    Details model view

edit_form(*obj=None*)
    Instantiate model editing form and return it.

    Override to implement custom behavior.

edit_view(**args*, ***kwargs*)
    Edit model view

get_actions_list()
    Return a list and a dictionary of allowed actions.

get_column_name(*field*)
    Return a human-readable column name.

> **Parameters field** – Model field name.

get_count_query()
    Return a the count query for the model type

    A `query(self.model).count()` approach produces an excessive subquery, so `query(func.count('*'))` should be used instead.

    See commit `#45a2723` for details.

get_create_form()
    Create form class for model creation view.

    Override to implement customized behavior.

get_delete_form()
    Create form class for model delete view.

    Override to implement customized behavior.

get_details_columns()
    Returns a list of the model field names in the details view. If *column_details_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

get_edit_form()
    Create form class for model editing view.

    Override to implement customized behavior.

get_filter_arg(*index*, *flt*)
    Given a filter *flt*, return a unique name for that filter in this view.

    Does not include the *flt[n]_* portion of the filter name.

> **Parameters**
>
> - **index** – Filter index in _filters array

- **flt** – Filter instance

get_filters()
> Return a list of filter objects.
>
> If your model backend implementation does not support filters, override this method and return *None*.

get_form()
> Get form class.
>
> If `self.form` is set, will return it and will call `self.scaffold_form` otherwise.
>
> Override to implement customized behavior.

get_list(*page*, *sort_column*, *sort_desc*, *search*, *filters*, *execute=True*, *page_size=None*)
> Return records from the database.
>
> > **Parameters**
> >
> > - **page** – Page number
> >
> > - **sort_column** – Sort column name
> >
> > - **sort_desc** – Descending or ascending sort
> >
> > - **search** – Search query
> >
> > - **execute** – Execute query immediately? Default is *True*
> >
> > - **filters** – List of filter tuples
> >
> > - **page_size** – Number of results. Defaults to ModelView's page_size. Can be overriden to change the page_size limit. Removing the page_size limit requires setting page_size to 0 or False.

get_list_columns()
> Returns a list of the model field names. If *column_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

get_list_form()
> Get form class for the editable list view.
>
> Uses only validators from *form_args* to build the form class.
>
> Allows overriding the editable list view field/widget. For example:

```python
from flask_admin.model.fields import ListEditableFieldList
from flask_admin.model.widgets import XEditableWidget

class CustomWidget(XEditableWidget):
    def get_kwargs(self, subfield, kwargs):
        if subfield.type == 'TextAreaField':
            kwargs['data-type'] = 'textarea'
            kwargs['data-rows'] = '20'
        # elif: kwargs for other fields

        return kwargs

class CustomFieldList(ListEditableFieldList):
    widget = CustomWidget()

class MyModelView(BaseModelView):
    def get_list_form(self):
        return self.scaffold_list_form(CustomFieldList)
```

get_list_value(*context*, *model*, *name*)

    Returns the value to be displayed in the list view

        Parameters

- **context** – jinja2.runtime.Context

- **model** – Model instance

- **name** – Field name

get_one(*id*)

    Return a single model by its id.

        Parameters **id** – Model id

get_pk_value(*model*)

    Return the primary key value from a model object. If there are multiple primary keys, they're encoded into string representation.

get_query()

    Return a query for the model type.

    If you override this method, don't forget to override *get_count_query* as well.

    This method can be used to set a "persistent filter" on an index_view.

    Example:

```python
class MyView(ModelView):
    def get_query(self):
        return super(MyView, self).get_query().filter(User.username == current_user.username
```

get_save_return_url(*model*, *is_created=False*)

    Return url where user is redirected after successful form save.

        Parameters

- **model** – Saved object

- **is_created** – Whether new object was created or existing one was updated

    For example, redirect use to object details view after form save:

```python
class MyModelView(ModelView):
    can_view_details = True

    def get_save_return_url(self, model, is_created):
        return self.get_url('.details_view', id=model.id)
```

get_sortable_columns()

    Returns a dictionary of the sortable columns. Key is a model field name and value is sort column (for example - attribute).

    If *column_sortable_list* is set, will use it. Otherwise, will call *scaffold_sortable_columns* to get them from the model.

get_url(*endpoint*, ***kwargs*)

    Generate URL for the endpoint. If you want to customize URL generation logic (persist some query string argument, for example), this is right place to do it.

        Parameters

- **endpoint** – Flask endpoint name

- **kwargs** – Arguments for *url_for*

handle_action(*return_view=None*)
> Handle action request.

>> Parameters **return_view** – Name of the view to return to after the request. If not provided, will return user to the return url in the form or the list view.

inaccessible_callback(*name*, ***kwargs*)
> Handle the response to inaccessible views.

> By default, it throw HTTP 403 error. Override this method to customize the behaviour.

index_view(**args*, ***kwargs*)
> List view

init_actions()
> Initialize list of actions for the current administrative view.

init_search()
> Initialize search. Returns *True* if search is supported for this view.

> For SQLAlchemy, this will initialize internal fields: list of column objects used for filtering, etc.

is_accessible()
> Override this method to add permission checks.

> Flask-Admin does not make any assumptions about the authentication system used in your application, so it is up to you to implement it.

> By default, it will allow access for everyone.

is_editable(*name*)
> Verify if column is editable.

>> Parameters **name** – Column name.

is_sortable(*name*)
> Verify if column is sortable.

> Not case-sensitive.

>> Parameters **name** – Column name.

is_valid_filter(*filter*)
> Verify that the provided filter object is valid.

> Override in model backend implementation to verify if the provided filter type is allowed.

>> Parameters **filter** – Filter object to verify.

is_visible()
> Override this method if you want dynamically hide or show administrative views from Flask-Admin menu structure

> By default, item is visible in menu.

> Please note that item should be both visible and accessible to be displayed in menu.

list_form(*obj=None*)
> Instantiate model editing form for list view and return it.

> Override to implement custom behavior.

on_form_prefill(*form*, *id*)
> Perform additional actions to pre-fill the edit form.

Called from edit_view, if the current action is rendering the form rather than receiving client side input, after default pre-filling has been performed.

By default does nothing.

You only need to override this if you have added custom fields that depend on the database contents in a way that Flask-admin can't figure out by itself. Fields that were added by name of a normal column or relationship should work out of the box.

> **Parameters**
>
> > • **form** – Form instance
> >
> > • **id** – id of the object that is going to be edited

on_model_change(*form*, *model*, *is_created*)

Perform some actions after a model is created or updated.

Called from create_model and update_model in the same transaction (if it has any meaning for a store backend).

By default does nothing.

> **Parameters**
>
> > • **form** – Form used to create/update model
> >
> > • **model** – Model that will be created/updated
> >
> > • **is_created** – Will be set to True if model was created and to False if edited

on_model_delete(*model*)

Perform some actions before a model is deleted.

Called from delete_model in the same transaction (if it has any meaning for a store backend).

By default do nothing.

render(*template*, ***kwargs*)

Render template

> **Parameters**
>
> > • **template** – Template path to render
> >
> > • **kwargs** – Template arguments

scaffold_auto_joins()

Return a list of joined tables by going through the displayed columns.

scaffold_filters(*name*)

Return list of enabled filters

scaffold_form()

Create form from the model.

scaffold_inline_form_models(*form_class*)

Contribute inline models to the form

> **Parameters form_class** – Form class

scaffold_list_columns()

Return a list of columns from the model.

scaffold_list_form(*custom_fieldlist=<class   'flask_admin.model.fields.ListEditableFieldList'>*, *validators=None*)

Create form for the *index_view* using only the columns from *self.column_editable_list*.

> **Parameters**
>
> - **validators** – *form_args* dict with only validators {'name': {'validators': [required()]}}
>
> - **custom_fieldlist** – A WTForm FieldList class. By default, *ListEditableFieldList*.

scaffold_pk()
> Return the primary key name(s) from a model If model has single primary key, will return a string and tuple otherwise

scaffold_sortable_columns()
> Return a dictionary of sortable columns. Key is column name, value is sort column/field.

update_model(*form*, *model*)
> Update model from form.
>
> > **Parameters**
> >
> > - **form** – Form instance
> >
> > - **model** – Model instance

validate_form(*form*)
> Validate the form on submit.
>
> > **Parameters form** – Form to validate

4.11 `flask_admin.contrib.mongoengine`

MongoEngine model backend implementation.

class ModelView(*model*, *name=None*, *category=None*, *endpoint=None*, *url=None*, *static_folder=None*, *menu_class_name=None*, *menu_icon_type=None*, *menu_icon_value=None*)
> MongoEngine model scaffolding.
>
> Class inherits configuration options from [`BaseModelView`](#) and they're not displayed here.

column_filters = None
> Collection of the column filters.
>
> Can contain either field names or instances of `flask_admin.contrib.mongoengine.filters.BaseFilter` classes.
>
> For example:

```python
class MyModelView(BaseModelView):
    column_filters = ('user', 'email')
```

> or:

```python
class MyModelView(BaseModelView):
    column_filters = (BooleanEqualFilter(User.name, 'Name'))
```

column_type_formatters = {<class 'mongoengine.base.datastructures.BaseList'>: <function list_formatter at 0x7fce
> Customized type formatters for MongoEngine backend

filter_converter = <flask_admin.contrib.mongoengine.filters.FilterConverter object>
> Field to filter converter.
>
> Override this attribute to use a non-default converter.

model_form_converter = <class 'flask_admin.contrib.mongoengine.form.CustomModelConverter'>
> Model form conversion class. Use this to implement custom field conversion logic.

> Custom class should be derived from the *flask_admin.contrib.mongoengine.form.CustomModelConverter*.

> For example:

```python
class MyModelConverter(AdminModelConverter):
    pass

class MyAdminView(ModelView):
    model_form_converter = MyModelConverter
```

allowed_search_types = (<class 'mongoengine.fields.StringField'>, <class 'mongoengine.fields.URLField'>, <class '
> List of allowed search field types.

form_subdocuments = None
> Subdocument configuration options.

> This field accepts dictionary, where key is field name and value is either dictionary or instance of the *flask_admin.contrib.EmbeddedForm*.

> Consider following example:

```python
class Comment(db.EmbeddedDocument):
    name = db.StringField(max_length=20, required=True)
    value = db.StringField(max_length=20)

class Post(db.Document):
    text = db.StringField(max_length=30)
    data = db.EmbeddedDocumentField(Comment)

class MyAdmin(ModelView):
    form_subdocuments = {
        'data': {
            'form_columns': ('name',)
        }
    }
```

> In this example, *Post* model has child *Comment* subdocument. When generating form for *Comment* embedded document, Flask-Admin will only create *name* field.

> It is also possible to use class-based embedded document configuration:

```python
class CommentEmbed(EmbeddedForm):
    form_columns = ('name',)

class MyAdmin(ModelView):
    form_subdocuments = {
        'data': CommentEmbed()
    }
```

> Arbitrary depth nesting is supported:

```python
class SomeEmbed(EmbeddedForm):
    form_excluded_columns = ('test',)

class CommentEmbed(EmbeddedForm):
    form_columns = ('name',)
    form_subdocuments = {
        'inner': SomeEmbed()
```

```
        }

    class MyAdmin(ModelView):
        form_subdocuments = {
            'data': CommentEmbed()
        }
```

There's also support for forms embedded into *ListField*. All you have to do is to create nested rule with *None* as a name. Even though it is slightly confusing, but that's how Flask-MongoEngine creates form fields embedded into ListField:

```
    class Comment(db.EmbeddedDocument):
        name = db.StringField(max_length=20, required=True)
        value = db.StringField(max_length=20)

    class Post(db.Document):
        text = db.StringField(max_length=30)
        data = db.ListField(db.EmbeddedDocumentField(Comment))

    class MyAdmin(ModelView):
        form_subdocuments = {
            'data': {
                'form_subdocuments': {
                    None: {
                        'form_columns': ('name',)
                    }
                }

            }
        }
```

action_view(**args*, ***kwargs*)
    Mass-model action view.

after_model_change(*form*, *model*, *is_created*)
    Perform some actions after a model was created or updated and committed to the database.

    Called from create_model after successful database commit.

    By default does nothing.

        Parameters

            • **form** – Form used to create/update model

            • **model** – Model that was created/updated

            • **is_created** – True if model was created, False if model was updated

after_model_delete(*model*)
    Perform some actions after a model was deleted and committed to the database.

    Called from delete_model after successful database commit (if it has any meaning for a store backend).

    By default does nothing.

        Parameters model – Model that was deleted

ajax_update(**args*, ***kwargs*)
    Edits a single column of a record in list view.

allowed_search_types = (<class 'mongoengine.fields.StringField'>, <class 'mongoengine.fields.URLField'>, <class '
    List of allowed search field types.

---

create_blueprint(*admin*)
Create Flask blueprint.

create_form(*obj=None*)
Instantiate model creation form and return it.

Override to implement custom behavior.

create_model(*form*)
Create model helper

> Parameters **form** – Form instance

create_view(**args*, ***kwargs*)
Create model view

delete_form()
Instantiate model delete form and return it.

Override to implement custom behavior.

The delete form originally used a GET request, so delete_form accepts both GET and POST request for backwards compatibility.

delete_model(*model*)
Delete model helper

> Parameters **model** – Model instance

delete_view(**args*, ***kwargs*)
Delete model view. Only POST method is allowed.

details_view(**args*, ***kwargs*)
Details model view

edit_form(*obj=None*)
Instantiate model editing form and return it.

Override to implement custom behavior.

edit_view(**args*, ***kwargs*)
Edit model view

get_actions_list()
Return a list and a dictionary of allowed actions.

get_column_name(*field*)
Return a human-readable column name.

> Parameters **field** – Model field name.

get_create_form()
Create form class for model creation view.

Override to implement customized behavior.

get_delete_form()
Create form class for model delete view.

Override to implement customized behavior.

get_details_columns()
Returns a list of the model field names in the details view. If *column_details_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

---

get_edit_form()
   Create form class for model editing view.

   Override to implement customized behavior.

get_filter_arg(*index*, *flt*)
   Given a filter *flt*, return a unique name for that filter in this view.

   Does not include the *flt[n]_* portion of the filter name.

   > **Parameters**
   >
   > - **index** – Filter index in _filters array
   >
   > - **flt** – Filter instance

get_filters()
   Return a list of filter objects.

   If your model backend implementation does not support filters, override this method and return *None*.

get_form()
   Get form class.

   If `self.form` is set, will return it and will call `self.scaffold_form` otherwise.

   Override to implement customized behavior.

get_list(*page*, *sort_column*, *sort_desc*, *search*, *filters*, *execute=True*, *page_size=None*)
   Get list of objects from MongoEngine

   > **Parameters**
   >
   > - **page** – Page number
   >
   > - **sort_column** – Sort column
   >
   > - **sort_desc** – Sort descending
   >
   > - **search** – Search criteria
   >
   > - **filters** – List of applied filters
   >
   > - **execute** – Run query immediately or not
   >
   > - **page_size** – Number of results. Defaults to ModelView's page_size. Can be overriden to change the page_size limit. Removing the page_size limit requires setting page_size to 0 or False.

get_list_columns()
   Returns a list of the model field names. If *column_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

get_list_form()
   Get form class for the editable list view.

   Uses only validators from *form_args* to build the form class.

   Allows overriding the editable list view field/widget. For example:

```python
from flask_admin.model.fields import ListEditableFieldList
from flask_admin.model.widgets import XEditableWidget

class CustomWidget(XEditableWidget):
    def get_kwargs(self, subfield, kwargs):
        if subfield.type == 'TextAreaField':
            kwargs['data-type'] = 'textarea'
```

```
            kwargs['data-rows'] = '20'
        # elif: kwargs for other fields

        return kwargs

class CustomFieldList(ListEditableFieldList):
    widget = CustomWidget()

class MyModelView(BaseModelView):
    def get_list_form(self):
        return self.scaffold_list_form(CustomFieldList)
```

get_list_value(*context*, *model*, *name*)
    Returns the value to be displayed in the list view

    Parameters

- **context** – jinja2.runtime.Context

- **model** – Model instance

- **name** – Field name

get_one(*id*)
    Return a single model instance by its ID

    Parameters id – Model ID

get_pk_value(*model*)
    Return the primary key value from the model instance

    Parameters model – Model instance

get_query()
    Returns the QuerySet for this view. By default, it returns all the objects for the current model.

get_save_return_url(*model*, *is_created=False*)
    Return url where user is redirected after successful form save.

    Parameters

- **model** – Saved object

- **is_created** – Whether new object was created or existing one was updated

For example, redirect use to object details view after form save:

```
class MyModelView(ModelView):
    can_view_details = True

    def get_save_return_url(self, model, is_created):
        return self.get_url('.details_view', id=model.id)
```

get_sortable_columns()
    Returns a dictionary of the sortable columns. Key is a model field name and value is sort column (for example - attribute).

    If *column_sortable_list* is set, will use it. Otherwise, will call *scaffold_sortable_columns* to get them from the model.

get_url(*endpoint*, ***kwargs*)
    Generate URL for the endpoint. If you want to customize URL generation logic (persist some query string argument, for example), this is right place to do it.

Parameters

- **endpoint** – Flask endpoint name
- **kwargs** – Arguments for *url_for*

handle_action(*return_view=None*)
    Handle action request.

    Parameters return_view – Name of the view to return to after the request. If not provided,
        will return user to the return url in the form or the list view.

handle_filter(*filter*)
    Postprocess (add joins, etc) for a filter.

    Parameters filter – Filter object to postprocess

inaccessible_callback(*name*, ***kwargs*)
    Handle the response to inaccessible views.

    By default, it throw HTTP 403 error. Override this method to customize the behaviour.

index_view(**args*, ***kwargs*)
    List view

init_actions()
    Initialize list of actions for the current administrative view.

init_search()
    Init search

is_accessible()
    Override this method to add permission checks.

    Flask-Admin does not make any assumptions about the authentication system used in your application, so
    it is up to you to implement it.

    By default, it will allow access for everyone.

is_editable(*name*)
    Verify if column is editable.

    Parameters name – Column name.

is_sortable(*name*)
    Verify if column is sortable.

    Not case-sensitive.

    Parameters name – Column name.

is_valid_filter(*filter*)
    Validate if the provided filter is a valid MongoEngine filter

    Parameters filter – Filter object

is_visible()
    Override this method if you want dynamically hide or show administrative views from Flask-Admin menu
    structure

    By default, item is visible in menu.

    Please note that item should be both visible and accessible to be displayed in menu.

list_form(*obj=None*)
> Instantiate model editing form for list view and return it.
>
> Override to implement custom behavior.

model_form_converter
> Model form conversion class. Use this to implement custom field conversion logic.
>
> Custom class should be derived from the *flask_admin.contrib.mongoengine.form.CustomModelConverter*.
>
> For example:

```python
class MyModelConverter(AdminModelConverter):
    pass

class MyAdminView(ModelView):
    model_form_converter = MyModelConverter
```

> alias of `CustomModelConverter`

object_id_converter
> Mongodb `_id` value conversion function. Default is *bson.ObjectId*. Use this if you are using String, Binary and etc.
>
> For example:

```python
class MyModelView(BaseModelView):
    object_id_converter = int
```

> or:

```python
class MyModelView(BaseModelView):
    object_id_converter = str
```

> alias of `ObjectId`

on_form_prefill(*form*, *id*)
> Perform additional actions to pre-fill the edit form.
>
> Called from edit_view, if the current action is rendering the form rather than receiving client side input, after default pre-filling has been performed.
>
> By default does nothing.
>
> You only need to override this if you have added custom fields that depend on the database contents in a way that Flask-admin can't figure out by itself. Fields that were added by name of a normal column or relationship should work out of the box.
>
> > **Parameters**
> >
> > - **form** – Form instance
> > - **id** – id of the object that is going to be edited

on_model_change(*form*, *model*, *is_created*)
> Perform some actions after a model is created or updated.
>
> Called from create_model and update_model in the same transaction (if it has any meaning for a store backend).
>
> By default does nothing.
>
> > **Parameters**

- **form** – Form used to create/update model

- **model** – Model that will be created/updated

- **is_created** – Will be set to True if model was created and to False if edited

on_model_delete(*model*)
> Perform some actions before a model is deleted.
>
> Called from delete_model in the same transaction (if it has any meaning for a store backend).
>
> By default do nothing.

render(*template*, ***kwargs*)
> Render template
>
> > **Parameters**
> >
> > - **template** – Template path to render
> >
> > - **kwargs** – Template arguments

scaffold_filters(*name*)
> Return filter object(s) for the field
>
> > **Parameters** **name** – Either field name or field instance

scaffold_form()
> Create form from the model.

scaffold_list_columns()
> Scaffold list columns

scaffold_list_form(*custom_fieldlist=<class* *'flask_admin.model.fields.ListEditableFieldList'>*, *validators=None*)
> Create form for the *index_view* using only the columns from *self.column_editable_list*.
>
> > **Parameters**
> >
> > - **validators** – *form_args* dict with only validators {'name': {'validators': [required()]}}
> >
> > - **custom_fieldlist** – A WTForm FieldList class. By default, *ListEditableFieldList*.

scaffold_sortable_columns()
> Return a dictionary of sortable columns (name, field)

update_model(*form*, *model*)
> Update model helper
>
> > **Parameters**
> >
> > - **form** – Form instance
> >
> > - **model** – Model instance to update

validate_form(*form*)
> Validate the form on submit.
>
> > **Parameters** **form** – Form to validate

4.12 `flask_admin.contrib.mongoengine.fields`

class **ModelFormField**(*model*, *view*, *form_class*, *form_opts=None*, ***kwargs*)
> Customized ModelFormField for MongoEngine EmbeddedDocuments.

class **MongoFileField**(*label=None*, *validators=None*, ***kwargs*)
    GridFS file field.

class **MongoImageField**(*label=None*, *validators=None*, ***kwargs*)
    GridFS image field.

4.13 `flask_admin.contrib.peewee`

Peewee model backend implementation.

class **ModelView**(*model*, *name=None*, *category=None*, *endpoint=None*, *url=None*, *static_folder=None*,
            menu_class_name=None, *menu_icon_type=None*, *menu_icon_value=None*)
    Class inherits configuration options from *BaseModelView* and they're not displayed here.

> **column_filters = None**
>   Collection of the column filters.
>
>   Can contain either field names or instances of `flask_admin.contrib.peewee.filters.BaseFilter`
>   classes.
>
>   For example:

```
class MyModelView(BaseModelView):
    column_filters = ('user', 'email')
```

> or:

```
class MyModelView(BaseModelView):
    column_filters = (BooleanEqualFilter(User.name, 'Name'))
```

> **filter_converter = <flask_admin.contrib.peewee.filters.FilterConverter object>**
>   Field to filter converter.
>
>   Override this attribute to use non-default converter.

> **model_form_converter = <class 'flask_admin.contrib.peewee.form.CustomModelConverter'>**
>   Model form conversion class. Use this to implement custom field conversion logic.
>
>   For example:

```
class MyModelConverter(AdminModelConverter):
    pass

class MyAdminView(ModelView):
    model_form_converter = MyModelConverter
```

> **inline_model_form_converter = <class 'flask_admin.contrib.peewee.form.InlineModelConverter'>**
>   Inline model conversion class. If you need some kind of post-processing for inline forms, you can cus-
>   tomize behavior by doing something like this:

```
class MyInlineModelConverter(AdminModelConverter):
    def post_process(self, form_class, info):
        form_class.value = TextField('value')
        return form_class

class MyAdminView(ModelView):
    inline_model_form_converter = MyInlineModelConverter
```

fast_mass_delete = False

> If set to *False* and user deletes more than one model using actions, all models will be read from the database and then deleted one by one giving Peewee chance to manually cleanup any dependencies (many-to-many relationships, etc).
>
> If set to True, will run DELETE statement which is somewhat faster, but might leave corrupted data if you forget to configure DELETE CASCADE for your model.

inline_models = None

> Inline related-model editing for models with parent to child relation.
>
> Accept enumerable with one of the values:
>
> 1.Child model class:

```
class MyModelView(ModelView):
    inline_models = (Post,)
```

> 2.Child model class and additional options:

```
class MyModelView(ModelView):
    inline_models = [(Post, dict(form_columns=['title']))]
```

> 3.Django-like `InlineFormAdmin` class instance:

```
class MyInlineModelForm(InlineFormAdmin):
    form_columns = ('title', 'date')

class MyModelView(ModelView):
    inline_models = (MyInlineModelForm(MyInlineModel),)
```

> You can customize generated field name by:
>
> 1.Using *form_name* property as option:
>
>> **class MyModelView(ModelView):** inline_models = ((Post, dict(form_label='Hello')))
>
> 2.Using field's related_name:
>
>> **class Model1(Base):** # ... pass
>>
>> **class Model2(Base):** # ... model1 = ForeignKeyField(related_name="model_twos")
>>
>> **class MyModel1View(Base):** inline_models = (Model2,) column_labels = {'model_ones': 'Hello'}

action_view(**args*, ***kwargs*)

> Mass-model action view.

after_model_change(*form*, *model*, *is_created*)

> Perform some actions after a model was created or updated and committed to the database.
>
> Called from create_model after successful database commit.
>
> By default does nothing.
>
>> **Parameters**
>>
>> • **form** – Form used to create/update model
>>
>> • **model** – Model that was created/updated
>>
>> • **is_created** – True if model was created, False if model was updated

after_model_delete(*model*)

Perform some actions after a model was deleted and committed to the database.

Called from delete_model after successful database commit (if it has any meaning for a store backend).

By default does nothing.

> **Parameters model** – Model that was deleted

ajax_update(**args*, ***kwargs*)

Edits a single column of a record in list view.

create_blueprint(*admin*)

Create Flask blueprint.

create_form(*obj=None*)

Instantiate model creation form and return it.

Override to implement custom behavior.

create_view(**args*, ***kwargs*)

Create model view

delete_form()

Instantiate model delete form and return it.

Override to implement custom behavior.

The delete form originally used a GET request, so delete_form accepts both GET and POST request for backwards compatibility.

delete_view(**args*, ***kwargs*)

Delete model view. Only POST method is allowed.

details_view(**args*, ***kwargs*)

Details model view

edit_form(*obj=None*)

Instantiate model editing form and return it.

Override to implement custom behavior.

edit_view(**args*, ***kwargs*)

Edit model view

get_actions_list()

Return a list and a dictionary of allowed actions.

get_column_name(*field*)

Return a human-readable column name.

> **Parameters field** – Model field name.

get_create_form()

Create form class for model creation view.

Override to implement customized behavior.

get_delete_form()

Create form class for model delete view.

Override to implement customized behavior.

get_details_columns()

Returns a list of the model field names in the details view. If *column_details_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

`get_edit_form``()`
    Create form class for model editing view.

    Override to implement customized behavior.

`get_filter_arg``(`*index*`, `*flt*`)`
    Given a filter *flt*, return a unique name for that filter in this view.

    Does not include the *flt[n]_* portion of the filter name.

> **Parameters**
> - **`index`** – Filter index in _filters array
> - **`flt`** – Filter instance

`get_filters``()`
    Return a list of filter objects.

    If your model backend implementation does not support filters, override this method and return *None*.

`get_form``()`
    Get form class.

    If `self.form` is set, will return it and will call `self.scaffold_form` otherwise.

    Override to implement customized behavior.

`get_list``(`*page*`, `*sort_column*`, `*sort_desc*`, `*search*`, `*filters*`, `*execute=True*`, `*page_size=None*`)`
    Return records from the database.

> **Parameters**
> - **`page`** – Page number
> - **`sort_column`** – Sort column name
> - **`sort_desc`** – Descending or ascending sort
> - **`search`** – Search query
> - **`filters`** – List of filter tuples
> - **`execute`** – Execute query immediately? Default is *True*
> - **`page_size`** – Number of results. Defaults to ModelView's page_size. Can be overriden to change the page_size limit. Removing the page_size limit requires setting page_size to 0 or False.

`get_list_columns``()`
    Returns a list of the model field names. If *column_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

`get_list_form``()`
    Get form class for the editable list view.

    Uses only validators from *form_args* to build the form class.

    Allows overriding the editable list view field/widget. For example:

```python
from flask_admin.model.fields import ListEditableFieldList
from flask_admin.model.widgets import XEditableWidget

class CustomWidget(XEditableWidget):
    def get_kwargs(self, subfield, kwargs):
        if subfield.type == 'TextAreaField':
            kwargs['data-type'] = 'textarea'
```

```
            kwargs['data-rows'] = '20'
        # elif: kwargs for other fields

        return kwargs

class CustomFieldList(ListEditableFieldList):
    widget = CustomWidget()

class MyModelView(BaseModelView):
    def get_list_form(self):
        return self.scaffold_list_form(CustomFieldList)
```

get_list_value(*context*, *model*, *name*)
  Returns the value to be displayed in the list view

  Parameters

   - **context** – jinja2.runtime.Context

   - **model** – Model instance

   - **name** – Field name

get_save_return_url(*model*, *is_created=False*)
  Return url where user is redirected after successful form save.

  Parameters

   - **model** – Saved object

   - **is_created** – Whether new object was created or existing one was updated

  For example, redirect use to object details view after form save:

```
class MyModelView(ModelView):
    can_view_details = True

    def get_save_return_url(self, model, is_created):
        return self.get_url('.details_view', id=model.id)
```

get_sortable_columns()
  Returns a dictionary of the sortable columns. Key is a model field name and value is sort column (for example - attribute).

  If *column_sortable_list* is set, will use it. Otherwise, will call *scaffold_sortable_columns* to get them from the model.

get_url(*endpoint*, ***kwargs*)
  Generate URL for the endpoint. If you want to customize URL generation logic (persist some query string argument, for example), this is right place to do it.

  Parameters

   - **endpoint** – Flask endpoint name

   - **kwargs** – Arguments for *url_for*

handle_action(*return_view=None*)
  Handle action request.

  Parameters **return_view** – Name of the view to return to after the request. If not provided, will return user to the return url in the form or the list view.

handle_filter(*filter*)
Postprocess (add joins, etc) for a filter.

> **Parameters filter** – Filter object to postprocess

inaccessible_callback(*name*, ***kwargs*)
Handle the response to inaccessible views.

By default, it throw HTTP 403 error. Override this method to customize the behaviour.

index_view(**args*, ***kwargs*)
List view

init_actions()
Initialize list of actions for the current administrative view.

is_accessible()
Override this method to add permission checks.

Flask-Admin does not make any assumptions about the authentication system used in your application, so it is up to you to implement it.

By default, it will allow access for everyone.

is_editable(*name*)
Verify if column is editable.

> **Parameters name** – Column name.

is_sortable(*name*)
Verify if column is sortable.

Not case-sensitive.

> **Parameters name** – Column name.

is_visible()
Override this method if you want dynamically hide or show administrative views from Flask-Admin menu structure

By default, item is visible in menu.

Please note that item should be both visible and accessible to be displayed in menu.

list_form(*obj=None*)
Instantiate model editing form for list view and return it.

Override to implement custom behavior.

on_form_prefill(*form*, *id*)
Perform additional actions to pre-fill the edit form.

Called from edit_view, if the current action is rendering the form rather than receiving client side input, after default pre-filling has been performed.

By default does nothing.

You only need to override this if you have added custom fields that depend on the database contents in a way that Flask-admin can't figure out by itself. Fields that were added by name of a normal column or relationship should work out of the box.

> **Parameters**
>
> - **form** – Form instance
>
> - **id** – id of the object that is going to be edited

---

on_model_change(*form*, *model*, *is_created*)
  Perform some actions after a model is created or updated.

  Called from create_model and update_model in the same transaction (if it has any meaning for a store backend).

  By default does nothing.

  Parameters

  - **form** – Form used to create/update model
  - **model** – Model that will be created/updated
  - **is_created** – Will be set to True if model was created and to False if edited

on_model_delete(*model*)
  Perform some actions before a model is deleted.

  Called from delete_model in the same transaction (if it has any meaning for a store backend).

  By default do nothing.

render(*template*, ***kwargs*)
  Render template

  Parameters

  - **template** – Template path to render
  - **kwargs** – Template arguments

scaffold_list_form(*custom_fieldlist=<class 'flask_admin.model.fields.ListEditableFieldList'>*, *validators=None*)
  Create form for the *index_view* using only the columns from *self.column_editable_list*.

  Parameters

  - **validators** – *form_args* dict with only validators {'name': {'validators': [required()]}}
  - **custom_fieldlist** – A WTForm FieldList class. By default, *ListEditableFieldList*.

validate_form(*form*)
  Validate the form on submit.

  Parameters form – Form to validate

4.14 `flask_admin.contrib.pymongo`

PyMongo model backend implementation.

class ModelView(*coll*, *name=None*, *category=None*, *endpoint=None*, *url=None*, *menu_class_name=None*, *menu_icon_type=None*, *menu_icon_value=None*)
  MongoEngine model scaffolding.

  Class inherits configuration options from [`BaseModelView`](#) and they're not displayed here.

column_filters = None
  Collection of the column filters.

  Should contain instances of `flask_admin.contrib.pymongo.filters.BasePyMongoFilter` classes.

  For example:

```
class MyModelView(BaseModelView):
    column_filters = (BooleanEqualFilter(User.name, 'Name'),)
```

action_view(**args*, ***kwargs*)
  Mass-model action view.

after_model_change(*form*, *model*, *is_created*)
  Perform some actions after a model was created or updated and committed to the database.

  Called from create_model after successful database commit.

  By default does nothing.

> **Parameters**
>
> > • **form** – Form used to create/update model
> >
> > • **model** – Model that was created/updated
> >
> > • **is_created** – True if model was created, False if model was updated

after_model_delete(*model*)
  Perform some actions after a model was deleted and committed to the database.

  Called from delete_model after successful database commit (if it has any meaning for a store backend).

  By default does nothing.

> **Parameters model** – Model that was deleted

ajax_update(**args*, ***kwargs*)
  Edits a single column of a record in list view.

create_blueprint(*admin*)
  Create Flask blueprint.

create_form(*obj=None*)
  Instantiate model creation form and return it.

  Override to implement custom behavior.

create_model(*form*)
  Create model helper

> **Parameters form** – Form instance

create_view(**args*, ***kwargs*)
  Create model view

delete_form()
  Instantiate model delete form and return it.

  Override to implement custom behavior.

  The delete form originally used a GET request, so delete_form accepts both GET and POST request for backwards compatibility.

delete_model(*model*)
  Delete model helper

> **Parameters model** – Model instance

delete_view(**args*, ***kwargs*)
  Delete model view. Only POST method is allowed.

details_view(**args*, ***kwargs*)
    Details model view

edit_form(*obj*)
    Create edit form from the MongoDB document

edit_view(**args*, ***kwargs*)
    Edit model view

get_actions_list()
    Return a list and a dictionary of allowed actions.

get_column_name(*field*)
    Return a human-readable column name.

        Parameters field – Model field name.

get_create_form()
    Create form class for model creation view.

    Override to implement customized behavior.

get_delete_form()
    Create form class for model delete view.

    Override to implement customized behavior.

get_details_columns()
    Returns a list of the model field names in the details view. If *column_details_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

get_edit_form()
    Create form class for model editing view.

    Override to implement customized behavior.

get_filter_arg(*index*, *flt*)
    Given a filter *flt*, return a unique name for that filter in this view.

    Does not include the *flt[n]_* portion of the filter name.

        Parameters

            • **index** – Filter index in _filters array

            • **flt** – Filter instance

get_filters()
    Return a list of filter objects.

    If your model backend implementation does not support filters, override this method and return *None*.

get_form()
    Get form class.

    If `self.form` is set, will return it and will call `self.scaffold_form` otherwise.

    Override to implement customized behavior.

get_list(*page*, *sort_column*, *sort_desc*, *search*, *filters*, *execute=True*, *page_size=None*)
    Get list of objects from MongoEngine

        Parameters

            • **page** – Page number

            • **sort_column** – Sort column

- **sort_desc** – Sort descending
- **search** – Search criteria
- **filters** – List of applied fiters
- **execute** – Run query immediately or not
- **page_size** – Number of results. Defaults to ModelView's page_size. Can be overriden to change the page_size limit. Removing the page_size limit requires setting page_size to 0 or False.

get_list_columns()
> Returns a list of the model field names. If *column_list* was set, returns it. Otherwise calls *scaffold_list_columns* to generate the list from the model.

get_list_form()
> Get form class for the editable list view.
>
> Uses only validators from *form_args* to build the form class.
>
> Allows overriding the editable list view field/widget. For example:

```python
from flask_admin.model.fields import ListEditableFieldList
from flask_admin.model.widgets import XEditableWidget

class CustomWidget(XEditableWidget):
    def get_kwargs(self, subfield, kwargs):
        if subfield.type == 'TextAreaField':
            kwargs['data-type'] = 'textarea'
            kwargs['data-rows'] = '20'
        # elif: kwargs for other fields

        return kwargs

class CustomFieldList(ListEditableFieldList):
    widget = CustomWidget()

class MyModelView(BaseModelView):
    def get_list_form(self):
        return self.scaffold_list_form(CustomFieldList)
```

get_list_value(*context*, *model*, *name*)
> Returns the value to be displayed in the list view

> **Parameters**
> - **context** – jinja2.runtime.Context
> - **model** – Model instance
> - **name** – Field name

get_one(*id*)
> Return single model instance by ID

> **Parameters id** – Model ID

get_pk_value(*model*)
> Return primary key value from the model instance

> **Parameters model** – Model instance

---

get_save_return_url(*model*, *is_created=False*)
    Return url where user is redirected after successful form save.

> **Parameters**
>
> > • **model** – Saved object
> >
> > • **is_created** – Whether new object was created or existing one was updated

> For example, redirect use to object details view after form save:

```python
class MyModelView(ModelView):
    can_view_details = True

    def get_save_return_url(self, model, is_created):
        return self.get_url('.details_view', id=model.id)
```

get_sortable_columns()
    Returns a dictionary of the sortable columns. Key is a model field name and value is sort column (for example - attribute).

    If *column_sortable_list* is set, will use it. Otherwise, will call *scaffold_sortable_columns* to get them from the model.

get_url(*endpoint*, ***kwargs*)
    Generate URL for the endpoint. If you want to customize URL generation logic (persist some query string argument, for example), this is right place to do it.

> **Parameters**
>
> > • **endpoint** – Flask endpoint name
> >
> > • **kwargs** – Arguments for *url_for*

handle_action(*return_view=None*)
    Handle action request.

> **Parameters** **return_view** – Name of the view to return to after the request. If not provided, will return user to the return url in the form or the list view.

handle_filter(*filter*)
    Postprocess (add joins, etc) for a filter.

> **Parameters** **filter** – Filter object to postprocess

inaccessible_callback(*name*, ***kwargs*)
    Handle the response to inaccessible views.

    By default, it throw HTTP 403 error. Override this method to customize the behaviour.

index_view(**args*, ***kwargs*)
    List view

init_actions()
    Initialize list of actions for the current administrative view.

init_search()
    Init search

is_accessible()
    Override this method to add permission checks.

    Flask-Admin does not make any assumptions about the authentication system used in your application, so it is up to you to implement it.

By default, it will allow access for everyone.

is_editable(*name*)
> Verify if column is editable.
>
> > **Parameters name** – Column name.

is_sortable(*name*)
> Verify if column is sortable.
>
> Not case-sensitive.
>
> > **Parameters name** – Column name.

is_valid_filter(*filter*)
> Validate if it is valid MongoEngine filter
>
> > **Parameters filter** – Filter object

is_visible()
> Override this method if you want dynamically hide or show administrative views from Flask-Admin menu structure
>
> By default, item is visible in menu.
>
> Please note that item should be both visible and accessible to be displayed in menu.

list_form(*obj=None*)
> Instantiate model editing form for list view and return it.
>
> Override to implement custom behavior.

on_form_prefill(*form*, *id*)
> Perform additional actions to pre-fill the edit form.
>
> Called from edit_view, if the current action is rendering the form rather than receiving client side input, after default pre-filling has been performed.
>
> By default does nothing.
>
> You only need to override this if you have added custom fields that depend on the database contents in a way that Flask-admin can't figure out by itself. Fields that were added by name of a normal column or relationship should work out of the box.
>
> > **Parameters**
> >
> > * **form** – Form instance
> >
> > * **id** – id of the object that is going to be edited

on_model_change(*form*, *model*, *is_created*)
> Perform some actions after a model is created or updated.
>
> Called from create_model and update_model in the same transaction (if it has any meaning for a store backend).
>
> By default does nothing.
>
> > **Parameters**
> >
> > * **form** – Form used to create/update model
> >
> > * **model** – Model that will be created/updated
> >
> > * **is_created** – Will be set to True if model was created and to False if edited

---

on_model_delete(*model*)
>   Perform some actions before a model is deleted.

>   Called from delete_model in the same transaction (if it has any meaning for a store backend).

>   By default do nothing.

render(*template*, ***kwargs*)
>   Render template

>   >   **Parameters**

>   >   >   • **template** – Template path to render

>   >   >   • **kwargs** – Template arguments

scaffold_filters(*attr*)
>   Return filter object(s) for the field

>   >   **Parameters** **name** – Either field name or field instance

scaffold_list_columns()
>   Scaffold list columns

scaffold_list_form(*custom_fieldlist=<class   'flask_admin.model.fields.ListEditableFieldList'>*, *validators=None*)
>   Create form for the *index_view* using only the columns from *self.column_editable_list*.

>   >   **Parameters**

>   >   >   • **validators** – *form_args* dict with only validators {'name': {'validators': [required()]}}

>   >   >   • **custom_fieldlist** – A WTForm FieldList class. By default, *ListEditableFieldList*.

>   Must be implemented in the child class.

scaffold_sortable_columns()
>   Return sortable columns dictionary (name, field)

update_model(*form*, *model*)
>   Update model helper

>   >   **Parameters**

>   >   >   • **form** – Form instance

>   >   >   • **model** – Model instance to update

validate_form(*form*)
>   Validate the form on submit.

>   >   **Parameters** **form** – Form to validate

4.15 `flask_admin.contrib.fileadmin`

class **FileAdmin**(*base_path*, *base_url=None*, *name=None*, *category=None*, *endpoint=None*, *url=None*, *verify_path=True*, *menu_class_name=None*, *menu_icon_type=None*, *menu_icon_value=None*)
>   Simple file-management interface.

>   >   **Parameters**

>   >   >   • **path** – Path to the directory which will be managed

- **base_url** – Optional base URL for the directory. Will be used to generate static links to the files. If not defined, a route will be created to serve uploaded files.

Sample usage:

```python
import os.path as op

from flask_admin import Admin
from flask_admin.contrib.fileadmin import FileAdmin

admin = Admin()

path = op.join(op.dirname(__file__), 'static')
admin.add_view(FileAdmin(path, '/static/', name='Static Files'))
```

can_upload = **True**
    Is file upload allowed.

can_delete = **True**
    Is file deletion allowed.

can_delete_dirs = **True**
    Is recursive directory deletion is allowed.

can_mkdir = **True**
    Is directory creation allowed.

can_rename = **True**
    Is file and directory renaming allowed.

allowed_extensions = **None**
    List of allowed extensions for uploads, in lower case.

    Example:

```python
class MyAdmin(FileAdmin):
    allowed_extensions = ('swf', 'jpg', 'gif', 'png')
```

editable_extensions = **()**
    List of editable extensions, in lower case.

    Example:

```python
class MyAdmin(FileAdmin):
    editable_extensions = ('md', 'html', 'txt')
```

list_template = **'admin/file/list.html'**
    File list template

upload_template = **'admin/file/form.html'**
    File upload template

mkdir_template = **'admin/file/form.html'**
    Directory creation (mkdir) template

rename_template = **'admin/file/rename.html'**
    Rename template

edit_template = **'admin/file/edit.html'**
    Edit template

can_download = **True**
    Is file download allowed.

---

delete(**args*, ***kwargs*)
 Delete view method

delete_form()
 Instantiate file delete form and return it.

 Override to implement custom behavior.

download(**args*, ***kwargs*)
 Download view method.

> Parameters **path** – File path.

edit(**args*, ***kwargs*)
 Edit view method

edit_form()
 Instantiate file editing form and return it.

 Override to implement custom behavior.

edit_modal = False
 Setting this to true will display the edit view as a modal dialog.

edit_template = 'admin/file/edit.html'
 Edit template

form_base_class
 Base form class. Will be used to create the upload, rename, edit, and delete form.

 Allows enabling CSRF validation and useful if you want to have custom contructor or override some fields.

 Example:

```python
class MyBaseForm(Form):
    def do_something(self):
        pass

class MyAdmin(FileAdmin):
    form_base_class = MyBaseForm
```

 alias of `BaseForm`

get_base_path()
 Return base path. Override to customize behavior (per-user directories, etc)

get_base_url()
 Return base URL. Override to customize behavior (per-user directories, etc)

get_delete_form()
 Create form class for model delete view.

 Override to implement customized behavior.

get_edit_form()
 Create form class for file editing view.

 Override to implement customized behavior.

get_name_form()
 Create form class for renaming and mkdir views.

 Override to implement customized behavior.

get_upload_form()
>   Upload form class for file upload view.
>
>   Override to implement customized behavior.

index(**args*, ***kwargs*)
>   Index view method
>
>   > **Parameters path** – Optional directory path. If not provided, will use the base directory

is_accessible_path(*path*)
>   Verify if the provided path is accessible for the current user.
>
>   Override to customize behavior.
>
>   > **Parameters path** – Relative path to the root

is_file_allowed(*filename*)
>   Verify if file can be uploaded.
>
>   Override to customize behavior.
>
>   > **Parameters filename** – Source file name

is_file_editable(*filename*)
>   Determine if the file can be edited.
>
>   Override to customize behavior.
>
>   > **Parameters filename** – Source file name

is_in_folder(*base_path*, *directory*)
>   Verify that *directory* is in *base_path* folder
>
>   > **Parameters**
>   >
>   > - **base_path** – Base directory path
>   >
>   > - **directory** – Directory path to check

mkdir(**args*, ***kwargs*)
>   Directory creation view method
>
>   > **Parameters path** – Optional directory path. If not provided, will use the base directory

mkdir_modal = False
>   Setting this to true will display the mkdir view as a modal dialog.

name_form()
>   Instantiate form used in rename and mkdir then return it.
>
>   Override to implement custom behavior.

on_directory_delete(*full_path*, *dir_name*)
>   Perform some actions after a directory has successfully been deleted.
>
>   Called from delete method
>
>   By default do nothing.

on_edit_file(*full_path*, *path*)
>   Perform some actions after a file has been successfully changed.
>
>   Called from edit method
>
>   By default do nothing.

on_file_delete(*full_path*, *filename*)
Perform some actions after a file has successfully been deleted.

Called from delete method

By default do nothing.

on_file_upload(*directory*, *path*, *filename*)
Perform some actions after a file has been successfully uploaded.

Called from upload method

By default do nothing.

on_mkdir(*parent_dir*, *dir_name*)
Perform some actions after a directory has successfully been created.

Called from mkdir method

By default do nothing.

on_rename(*full_path*, *dir_base*, *filename*)
Perform some actions after a file or directory has been renamed.

Called from rename method

By default do nothing.

rename(**args*, ***kwargs*)
Rename view method

rename_modal = False
Setting this to true will display the rename view as a modal dialog.

save_file(*path*, *file_data*)
Save uploaded file to the disk

> Parameters
>
> > • **path** – Path to save to
> >
> > • **file_data** – Werkzeug *FileStorage* object

upload(**args*, ***kwargs*)
Upload view method

> Parameters **path** – Optional directory path. If not provided, will use the base directory

upload_form()
Instantiate file upload form and return it.

Override to implement custom behavior.

upload_modal = False
Setting this to true will display the upload view as a modal dialog.

validate_form(*form*)
Validate the form on submit.

> Parameters **form** – Form to validate

4.16 `flask_admin.model.template`

macro(*name*)

> Jinja2 macro list column formatter.

> > **Parameters** **name** – Macro name in the current template

Changelog

5.1 1.3.0

- New feature: Edit models in the list view in a popup
- New feature: Read-only model details view
- Fixed XSS in column_editable_list values
- Improved navigation consistency in model create and edit views
- Ability to choose page size in model list view
- Updated client-side dependencies (jQuery, Select2, etc)
- Updated documentation and examples
- Updated translations
- Bug fixes

5.2 1.2.0

- Codebase was migrated to Flask-Admin GitHub organization
- Automatically inject Flask-WTF CSRF token to internal Flask-Admin forms
- MapBox v4 support for GeoAlchemy
- Updated translations with help of CrowdIn
- Show warning if field was ignored in form rendering rules
- Simple AppEngine backend
- Optional support for Font Awesome in templates and menus
- Bug fixes

5.3 1.1.0

Mostly bug fix release. Highlights:

- Inline model editing on the list page

- FileAdmin refactoring and fixes

- FileUploadField and ImageUploadField will work with Required() validator

- Bug fixes

5.4 1.0.9

Highlights:

- Bootstrap 3 support

- WTForms 2.x support

- Updated DateTime picker

- SQLAlchemy backend: support for complex sortables, ability to search for related models, model inheritance support

- Customizable URL generation logic for all views

- New generic filter types: in list, empty, date range

- Added the `geoa` contrib module, for working with geoalchemy2

- Portugese translation

- Lots of bug fixes

Support

Python 2.6 - 2.7 and 3.3 - 3.4.

Indices And Tables

- genindex
- modindex
- search
